A man were better twenty times be a bandog and bark,
 Than here, among such a sort, be parish priest or clerk,
 Where he shall never be at rest one pissing-while a day,
 But he must trudge about the town, this way and that way,
 Here to a drab, there to a thief, his shoes to tear and rent,
 And, that which is worst of all, at every knave's commandment!
 I had not sit the space to drink two pots of ale
 But Gammer Gurton's sorry boy was straightway at my tail,
 And she was sick, and I must come—to do I wot not what!
 If once her finger's end but ache, "Trudge! Call for Doctor Rat!"*

*Gammer Gurton's Needle, Act IV, scene i. 1575.

Harold W. Brunn

Harold W. Brunn, Executive Secretary of the Minnesota State Medical Association, has been elected President-elect and a member of the Board of Directors of the American Association of Medical Society Executives (AAMSE). He previously served as Secretary Treasurer and Director. AAMSE is a national organization of executive directors of national, state and county medical associations and societies.

Brunn was elected President at the annual meeting of AAMSE Saturday, June 23, held in conjunction with the 122nd Annual Convention of the American Medical Association in New York City.

The Fate of the Abandoned Bladder

JOHN T. CAMPBELL, M.D.,* JAMES H. DeWEERD, M.D.* and DAVID C. UTZ, M.D.*

RECENT REVIEWS indicate that if the defunctionalized bladder becomes the seat of retained purulent secretions, resulting in vesical empyema, then cystectomy is inevitable in the vast majority of reported cases, irrespective of the type of bladder disease.¹⁻⁸ Others point out that simple cystectomy is not without risk. Jaffe and associates⁵ present data suggesting that cystectomy associated with urinary diversion doubles the mortality rate, even for benign disease.

A retrospective study was designed to examine our surgical experience at the Mayo Clinic in which supravescical urinary diversion was done without concomitant cystectomy. Specifically, the fate of the abandoned bladder is in question for both benign and malignant disease.

Methods and Materials

During the three-year period from 1967 through 1969, 50 patients at the Mayo Clinic underwent supravescical urinary diversion without cystectomy. The patients' ages ranged from 15 days to 80 years; half the patients were male.

Basic disease processes included both malignant and benign entities (Table 1). Carcinoma accounted for 20 cases (40%) in the series. Neurogenic vesical dysfunction was present in 14. Congenital anomalies in another 11 cases included a wide range of obstructive features inevitably responsible for hydronephrosis, pyelonephritis, and renal destruction.

Indications for surgical intervention were related to symptoms, uncontrollable infection, deterioration of upper tracts, or the presence of carcinoma (Table 2). There were often several factors as surgical indications.

Modalities of urinary diversion are recorded in Table 3. Many patients had experienced the failure of previous surgical procedures. Not infrequently, patients were seen with advanced disease, which narrowed the possibilities of the surgi-

cal approach. The route of diversion oftentimes had to be tailored to the severity of the disease. Every procedure involved abandonment of the bladder. Most of the bladders were no longer suitable as a urinary reservoir.

The reasons for not doing cystectomy at the time of urinary diversion differed. For 27 patients, cystectomy could not be justified on the basis of the underlying disease or circumstance. In 18 patients with carcinoma of the bladder or cervix, cystectomy was either technically impossible because of bladder fixation or inadvisable because of the advanced stage of metastatic disease. In the remaining five patients, the bladder

abandonment was temporary.

Findings

Eight of the 50 patients had symptoms referable to the abandoned bladder (Table 4). Droplet hemorrhage through the urethra was a nuisance factor for two patients who had carcinoma of the bladder, but this was not associated with pain and did not require blood transfusion. Frankly bloody urethral discharge occurred in a 15-year-old boy who originally had urethral valves, and this led to the discovery of cystitis glandularis for which cystectomy was done. Two patients each had purulent foul discharge, characteristic of pyocystitis but without sepsis: one of the patients was managed successfully by saline lavage twice weekly for several weeks, and the other required no treatment and has subsequently been asymptomatic. Three patients had bladder spasms manifested by suprapubic discomfort, cramping, and a suprapubic mass; all three had underlying vesical carcinoma. Two of the three had total urethral obstruction with tumor; cystectomy was done in one and was impossible in the other. The third patient with bladder spasms had recurrent bladder tumor and radiation cystitis from radon-seed implants.

Comment

The source of fluids retained in obstructed isolated bladders remains only partially explained. Active mucosal transfer of water and ions and mucosal glandular secretions have been suggested as basic mechanisms of bladder fluid production.^{9,10} Others have claimed that, in the male, most fluid is derived from retrograde ejaculation or resting prostatic and genital secretions.¹¹ The retention of bladder fluid is asymptomatic unless infection supervenes.

All agree that obstruction of the vesical neck or urethra predisposes the abandoned bladder to retention of secretions and to infection. Animal studies lend credence to this concept.⁷ Once pyocystitis is established, management with systemic antibiotics and local lavage is useless unless the obstruction has been surgically removed. To this end, Spence and Allen¹² have recommended the creation of a vaginal vesicostomy for empyema of the abandoned bladder. Malek et al.⁶ believe that if a bladder will not empty it should be removed if circumstances permit.

In our experience, the abandoned bladder has not been a tremendous source of concern to surgeon or patient. Only eight of the 50 in our series had symptoms referable to the bladder. Of the four who ultimately required cystectomy, two had exstrophy as part of a deliberately staged cystectomy. Only two of the 50 had findings consistent with underlying pyocystitis; neither patient required cystectomy. This has not been the experience in other large series^{4,6,12} in which the symptoms of pyocystitis failed to respond to conservative management.

Bladder symptoms occurred relatively frequently in the patients with cancer, who comprised 40% of the patients in our series. Occasionally, tumor invasion was associated with obstruction of vesical neck and proximal urethra. In two patients (one male and one female), this progressed to its logical conclusion—a sealed bladder. In the female, the seal was penetrated by instrumentation, thus reestablishing drainage. The male underwent cystectomy, during which 500 ml of watery, tea-colored fluid were removed. Other bladder symptoms in the patients with cancer were relatively mild. Yet all 14 patients with carcinoma of the bladder died of their disease: 12 died within 18 months after urinary diversion.

Summary

The fate of the abandoned bladder was reviewed in 50 patients who had undergone urinary diversion without cystectomy. The series included 14 patients with advanced carcinoma of the bladder, all of whom died within four years after urinary diversion. Obstruction was the primary basis for the retained bladder secretions. Bladder symptoms including urethral purulent discharge, urethral droplet hemorrhage, and bladder spasms occurred in only eight patients; five of these had underlying carcinoma of the bladder. Cystectomy

was done in four patients, including two who had xstrophy, one who had cystitis glandularis, and one who had his bladder outlet sealed by tumor. Most patients with abandoned bladder were symptomatic, and most patients in whom symptoms developed were managed conservatively. In

our experience with the abandoned bladder after urinary diversion, the ultimate results have been sufficiently satisfying that, in the absence of outlet obstruction, we continue to favor leaving the bladder undisturbed, when cystectomy for underlying disease cannot be justified.

Duplay's Syndrome

This commonly observed calcifying tendinitis or peritendinitis involving the shoulder area constitutes one of the etiologic components of the supraspinatus syndrome. It was first described by Duplay (1896) as "scapulohumeral periarthrititis."

Cardinal symptoms consist of pain and limitation of motion of the shoulder joint. Calcification is frequently present in both shoulders and may long be asymptomatic. When pain does occur, it may be quite intense and often prevents sleep despite generous doses of narcotics. Three varieties of "frozen shoulder" have been described: (1) a localized form with general articular involvement, in persons under 40 years of age; (2) a degenerative form, in persons over 40 years of age; and (3) a posttraumatic form from a tear in the rotation cuff.

One theory concerning cause of the calcium deposition includes occlusion of the vessels of the tendon from hypertrophy of the tunica media. As in aseptic necrosis of the head of the humerus or elsewhere, local necrosis of the tissues occurs, followed by the deposition of calcium. Almost immediate relief may be obtained by opening the tendon capsule surgically. Many cases will respond promptly to the local injection of an anesthetic agent, as procaine and hydrocortisone. Irradiation of the area also affords gradual relief of pain and, in many instances, complete disappearance of the calcific deposit within a few months.

Health Officer Appointment

Mayor Lawrence D. Cohen of St. Paul announced today that Dr. Clarence E. Henke will be the chief health officer for the Division of Environmental Protection of the Community Services Department.

Dr. Henke, a native of South St. Paul, has since April 1, 1973, been a full-time staff member of the Ambulatory Care Section of St. Paul-Ramsey Hospital with responsibilities for organizing multiphasic and occupational health clinics and coordination of community health programs.

The Case of the Missing Vas

Unilateral Absence of the Vas Deferens

ROBERT B. BENJAMIN, M.D.* and ALAEDDIN MOGHADDAM, M.D.†

VASECTOMY HAS become one of the more common methods of contraception. It is estimated that over one million vasectomies are performed annually in the United States. One of the problems occasionally encountered during vasectomy is unilateral absence of the vas deferens. Knowledge regarding the significance of this anomaly is important to all surgeons who perform vasectomies. We have developed a *modus operandi* which will result in less trauma to those patients who are found to have unilateral absence of the vas deferens.

Congenital absence of the vas deferens was

*Department of General Surgery, St. Louis Park Medical Center, Minneapolis.

†Department of Urology, St. Louis Park Medical Center.

first reported by Demell in 1926.¹ Since then papers on *bilateral* absence of the vas deferens have been published.²⁻⁷ These earlier studies were done on patients complaining of *sterility*. This study concerns a group of *fertile* patients seen because they were seeking vasectomies for sterilization. We first reported these cases at the National Conference on Vasectomy in 1971. Since then other authors have reported unilateral absence of the vas deferens in patients undergoing vasectomy.⁸⁻¹⁰

Method

At the St. Louis Park Medical Center over a period of ten years (1960-1970), 3,000 vasectomies for sterilization were performed. Thirteen

TABLE
Vasectomy Patients with Congenital, Unilateral Absence of Vas Deferens

Patient	Age	Side on which vas was absent	X-ray findings	Findings on physical examination
Case 1 19-09-87	38	Left	Atrophic left kidney (less than 4 cm in length). Hypertrophy of right kidney —nearly 17 cm in length. Normal left ureter.	Vas deferens not palpable on left.
Case 2 17-60-38	27	Left	Absence of left kidney. Hypertrophy of right kidney.	Vas deferens not palpable on left.
Case 3 19-83-62	22	Left	Crossed renal ectopia. Both kidneys found on right side with upper poles fused.	Vas deferens not palpable on left.
Case 4 16-26-71	31	Left	Absence of left kidney. Hypertrophy of right kidney.	Vas deferens not palpable on left. Left lobe of prostate is smaller. No seminal vesical palpated on left.
Case 5 18-08-91	34	Right	Absence of right kidney. Hypertrophy of left kidney.	Vas deferens not palpable on right.
Case 6 15-11-32	42	Right	Normal kidneys bilaterally.	Vas deferens not palpable on right.
Case 7 17-12-86	33	Left	Normal kidneys bilaterally.	Vas deferens not palpable on left.

Comment

Evaluation of the urinary tract in patients with unilateral absence of the vas deferens is more than a matter of academic curiosity. One should be aware of the serious implications of a congenital solitary kidney. Campbell states that one-fourth of his patients with a solitary kidney died of renal failure.⁷ Some investigators have shown that patients with a solitary kidney suffer a higher incidence of disease than do those with two normal kidneys.

Modus Operandi

During a vasectomy procedure, if one is unable to palpate a vas deferens on one side, we do not believe the patient should be subjected to a thorough dissection of the spermatic cord structures. It has been our experience that such explorations do not result in finding a vas deferens if one was not previously found by palpation. It is better to desist with the vasectomy after operating on the contralateral vas deferens. A sperm count will later prove whether the patient has only one vas deferens.

Summary

In our series of 3,000 patients undergoing vasectomies, seven were found to have congenital unilateral absence of the vas deferens, an incidence of 0.23% in *fertile* males. The diagnosis can be made by careful physical examination. If a vas deferens cannot be palpated, exploration of the spermatic cord is not likely to be fruitful and does not appear to be indicated. Excluding those cases where previous surgery for hernia or undescended testis has been performed, we have found that clinical evaluation of the spermatic cord was as reliable as exploration and dissection. Consequently, we advise no extended surgery in patients who are found, on palpation, to have only one vas deferens. These patients should be followed up with a semen examination two months following surgery. If no sperm are seen, the patient has then been proven to have only one vas deferens. In all patients with unilateral absence of the vas deferens, intravenous pyelograms should be obtained because of the probability of congenital absence of the ipsilateral kidney and ureter or other urinary tract abnormalities.

Embryology

The ureter is formed by a posterior budding of the wolffian duct which itself ultimately becomes the vas deferens. Thus, absence of the wolffian duct would be expected to result in absence of both the ureter and the vas deferens. This embryologic development is considerably different from that which occurs in *bilateral* absence of the vas deferens. In fertile males undergoing vasectomy for purposes of sterilization, unilateral absence of a vas deferens generally appears to be associated with absence or abnormality of the ipsilateral ureter and kidney, indicating that the wolffian duct has been absent from early embryonic life.^{6,7} An understanding of this embryology is important to surgeons who operate upon the vas deferens.

Traumatic Sudden Deafness

or

A Scuba Diver Gets It—In The Ear

JOSEPH H. LEEK, M.D.* and RICHARD L. RIESS, PH.D.†

SUDDEN DEAFNESS is a catastrophe that can befall an individual of any age. It may be fleeting or permanent, leaving a profound hearing deficit. The etiology has been speculative, with a viral or a vascular lesion being attributed as the cause for the majority of such cases.⁶ Treatment has been empirical and subject to much criticism.³

Goodhill recently suggested some etiologic features that relate to therapy.⁴ A patient, with symptoms similar to Goodhill's presented himself for treatment.

In 1968 Simmons⁶ was of the opinion that certain cases of sudden deafness might be the result of ruptures, breaks, or dislocations of intracochlear membranes. He reviewed 15 patients whose clinical pattern fitted this type of sudden deafness. Each had normal hearing in the affected ear prior to the incident and each could document exactly when the damage occurred—a "pop" was heard or felt immediately preceding the decrease in hearing. No vertigo was associated with this hearing loss and no vestibular symptoms occurred subsequently. No patient had any evidence of respiratory, cardiovascular or endocrine disease. To replace the label "etiology unknown," now applied to about 30% of sudden hearing loss, Simmons suggested the term "membrane rupture."

Goodhill,³ in his presidential address to the Trilogical Society in 1971, spoke about sudden deafness following physical exertion and presented four examples: (1) Following a scuba dive; (2) After numerous sit-ups; (3) Following an alcoholic debauch. (4) While cheering and rooting at a football game. Surgical intervention in the last three cases showed that these patients all had oval window perilymphatic fistulae.

One of four patients, suspected by Pullen⁵ of having possible intracochlear membrane rupture

causing sudden deafness, had sustained damage following scuba diving. Exploratory tympanotomy revealed a fistula of the round window, which was repaired with restoration of normal hearing.

The term "inner ear barotrauma" was suggested by Freeman² to describe sensori-neural hearing loss due to atmospheric pressure shifts. Five of his patients were divers who had difficulty clearing their ears on descent into the water. They had hearing losses which varied on audiogram from high tone sensori-neural defects to total loss of cochlear function. Freeman thought that none of these hearing defects could be attributed to decompression sickness. No surgical exploration was done on these patients. Goodhill⁴ postulated that round or oval window membrane rupture or rupture of both membranes could have occurred in these divers and that surgical repair of these perilymphatic fistulae might salvage the hearing in such individuals.

It was Goodhill's letter that motivated us to consider surgical exploration and possible repair when our patient described symptoms suggestive of inner ear barotrauma. Both the physical findings and an audiogram supported this impression. The potential urgency for instituting definitive care in this problem, as well as the often favorable outcome following surgical repair is illustrated in this case.

Case Report

A 19-year-old college student scuba diving in Lake Superior descended to 43 feet. Rushes of pain in his left ear forced him to ascend a few feet. Four or five repetitions of the descent were accompanied by the same type of pain so that he surfaced. He immediately noted pressure and fullness with a hearing defect and buzzing in the left ear. He had no vestibular symptoms. The following day he visited a physician who found no ear canal or drum abnormality and gave the opinion there had been middle ear trauma which would resolve spontaneously in a few days. He prescribed a topical

*Department of Otolaryngology, Duluth Clinic, Duluth, Minnesota.

†Department of Audiology, Duluth Clinic, Duluth, Minnesota.

ar solution.

The pressure, fullness, hearing loss, and tinnitus in the ear remained unchanged. We saw this patient on the eleventh day. The left ear appeared normal, and pneumatic massage of the drumhead revealed no abnormality. No disease was evident at the completion of a general physical examination.

Audiovestibular testing showed the Rinne test positive on the right, negative on the left and the Weber test lateralizing to the right, (using a tuning fork of 256 vibrations per second). The pure tone air and bone conduction audiogram (Figure) demonstrated a moderate sensori-neural loss. The speech reception threshold was 55 decibels but the speech discrimination score remained normal. There was mild recruitment but a negative short increment sensitivity index (SISI) response. Ice water caloric vestibular studies gave normal results.

Tympanotomy, done on the 14th day after the injury, disclosed a middle ear which was air-containing. No ossicular lesion was found. However, the round window niche seemed bottomless and, crossing this window, was a thin membranous strand. Glistening fluid pulsed on either side of the strand. When dry gelfoam was placed in the round window niche, it immediately became saturated with colorless perilymph. After preparing the bony margins of the window, repair was completed with a tissue plug of ear lobule fat to close the round window defect.

When the dressings were removed one week postoperatively, the patient immediately found that the hearing was improved. This was borne out by the postoperative audiogram (Figure), showing complete recovery. This has been sustained, at the time of this writing, for six months.

Discussion

The identification of inner ear barotrauma, re-

sulting in membranous rupture, gives a specific etiology for certain cases of sudden deafness.^{1,6} Some of these ruptures appear to be correctable by surgical repair with restoration of hearing. The diagnosis must be arrived at by careful evaluation. Obviously every case of sudden deafness is not secondary to a ruptured intracochlear membrane and unnecessary surgical explorations must be avoided. The basic clues appear in the history of onset, with the "popping" sensation felt so distinctly by an otherwise healthy patient after a specific exertional event. Characteristically he will be aware immediately of a hearing loss without vestibular symptoms. This sequence of events should alert the physician to consider barotrauma. If such a diagnosis can be supported by clinical evaluation and if spontaneous recovery does not occur during several days of bedrest, surgical intervention is in order.

Exploration of the middle ear, in an attempt to locate a perilymphatic fistula, should present no difficulty to an otologist trained in microsurgical techniques. A large round window membrane defect was in direct view when the middle ear of our reported patient was explored. If a bony overhang obscures a direct view of such a ruptured membrane, dry gelfoam can be used in the area of the window. If the gelfoam becomes repeatedly saturated with clear fluid, conclusive evidence of a fistula is demonstrated. After the surrounding bony surface is adequately

Figure—The left ear audiogram demonstrating the cochlear hearing defect in solid lines and the subsequent recovery in dotted lines.

prepared, a tissue plug or piece of gelfoam should serve as an adequate new membrane to seal the fistula.

Apparently a perilymphatic fistula of several days' duration does not seem to doom the cochlea to irreparable injury. Although the potential of contamination of the perilymph and the cerebrospinal fluid exists via the eustachian tube, evidently there is sufficient washing of the area by perilymph to act as a protective barrier.

A safe time interval between the trauma and

surgical exploration is unknown. In our case the lesion was fourteen days old. Emergency repair of such injuries is not proposed. Hospitalization, with bed rest, is recommended for seven to ten days. If no recovery ensues then surgical intervention is advisable. As long as eighteen days after the injury, rapid spontaneous recovery has been reported.⁷ In these instances, it is assumed that the fistula seals by secondary intention, accomplishing the same thing that we do with surgical repair.

Request for Physician's Art Work

For many years the Board of Editors of MINNESOTA MEDICINE has recognized and supported photographic and other artistic talents of the members of the Minnesota State Medical Association publishing cover pictures in color of their work. Our series of color covers have received much favorable comment and many journals have followed us in the use of color art in this manner.

We solicit color photographs including pictures of all art forms created by members of the Association. These must be technically excellent to show off the subject to its best advantage.

Although in the past we have printed cover pictures depicting many distant parts of the world, photographs of life in Minnesota will be given preference. Pictures will be returned if identified with the name and address of the physician. Please submit your picture as prospective cover subjects to the Editor of MINNESOTA MEDICINE, 375 Jackson St., St. Paul, Minnesota 55101.

one of the many things you need in an anticholinergic.

Pro-Banthine is provided in several different dosage forms and combinations which will meet virtually any clinical need. It is just as versatile in filling patient needs, among which are:

"Antiacid" action—Pro-Banthine® (propantheline bromide) reduces gastric secretory volume and resting total and free acid.

"Sustained" action—Pro-Banthine P.A.® (propantheline bromide) contains 30 mg. of the drug in the form of sustained-release or timed-release beads; on ingestion about half of the drug is released within an hour and the remainder continuously as earlier increments are metabolized.

High-level anticholinergic activity is maintained all day and all night in most patients with only two tablets every eight hours.

"Analgesic" action—Pro-Banthine helps to control the acid-spasm-pain complex.

A "diagnostic tool"—Pro-Banthine may be used parenterally to immobilize the duodenum for more revealing roentgenographic appraisal through hypotonic duodenography.

Pro-Banthine is considered adjunctive in total peptic ulcer therapy that may include diet, conventional antacids, bed rest, and other supportive measures.

Vigorous anticholinergic action — Pro-Banthine® Vials, 30 mg., are for intramuscular or intravenous use when prompt and vigorous anticholinergic action is required.

Mild anticholinergic action—Pro-Banthine® Half Strength, 7.5-mg. tablets, for more exact adjustment of maintenance dosage in mild to moderate gastrointestinal disorders.

Indications: Pro-Banthine is effective as adjunctive therapy in the treatment of peptic ulcer. Dosage must be adjusted to the individual.

Contraindications: Glaucoma, obstructive disease of the gastrointestinal tract, obstructive uropathy, intestinal atony, toxic megacolon, hiatal hernia associated with reflux esophagitis, or unstable cardiovascular adjustment in acute hemorrhage.

Warnings: Patients with severe cardiac disease should be given this medication with caution.

Fever and possibly heat stroke may occur due to anhidrosis. In theory a curare-like action may occur, with loss of voluntary muscle control. For such patients prompt and continuing artificial respiration should be applied until the drug effect has been exhausted.

Diarrhea in an ileostomy patient may indicate obstruction, and this possibility should be considered before administering Pro-Banthine.

Precautions: Since varying degrees of urinary hesitancy may be evidenced by elderly males with prostatic hypertrophy, such patients should be advised to micturate at the time of taking the medication.

Overdosage should be avoided in patients severely ill with ulcerative colitis.

Adverse Reactions: Varying degrees of drying of salivary secretions may occur as well as mydriasis and blurred vision. In addition the following adverse reactions have been reported: nervousness, drowsiness, dizziness, insomnia, headache, loss of the sense of taste, nausea, vomiting, constipation, impotence and allergic dermatitis.

Dosage and Administration: The recommended daily dosage for adult oral therapy is one 15-mg. tablet with meals and two at bedtime. Subsequent adjustment to the patient's requirements and tolerance must be made.

Pro-Banthine P.A.—Each tablet of Pro-Banthine P.A. (propantheline bromide) contains 30 mg. of the drug in the form of sustained-release or timed-release beads; on ingestion about half of the drug is released within an hour and the remainder continuously as earlier increments are metabolized. Thus the result is even, high-level anticholinergic activity maintained all day and all night in most patients with only two tablets daily. Some patients may require one tablet every eight hours.

The contraindications and precautions applicable to Pro-Banthine 15 mg. should be observed.

How Supplied: Pro-Banthine is supplied as tablets of 15 and 7.5 mg., as prolonged-acting tablets of 30 mg. and, for parenteral use, as serum-type vials of 30 mg.

Pro-Banthine®
brand of
propantheline bromide
a good option in peptic ulcer

A DOUBLE-DUTY DIURETIC

DYAZIDE

Trademark®

Each capsule contains 50 mg. of Dyrenium® (brand of triamterene)
and 25 mg. of hydrochlorothiazide.

GETS THE WATER OUT IN EDEMA

BRINGS DOWN BLOOD PRESSURE IN HYPERTENSION*

SPARES POTASSIUM IN BOTH

Before prescribing, see complete prescribing information in SK&F literature or *PDR*.

***Indications:** Edema associated with congestive heart failure, cirrhosis of the liver, the nephrotic syndrome; steroid-induced and idiopathic edema; edema resistant to other diuretic therapy. Also, mild to moderate hypertension.

Contraindications: Pre-existing elevated serum potassium. Hypersensitivity to either component. Continued use in progressive renal or hepatic dysfunction or developing hyperkalemia.

Warnings: Do not use dietary potassium supplements or potassium salts unless hypokalemia develops or dietary potassium intake is markedly impaired. Enteric-coated potassium salts may cause small bowel stenosis with or without ulceration. Hyperkalemia (> 5.4 mEq/L) has been reported in 4% of patients under 60 years, in 12% of patients over 60 years, and in less than 8% of patients overall. Rarely, cases have been associated with cardiac irregularities. Accordingly, check serum potassium during therapy, particularly in patients with suspected or confirmed renal insufficiency (e.g., elderly or diabetics). If hyperkalemia develops, substitute a thiazide alone. If spironolactone is used concomitantly with 'Dyazide', check serum potassium frequently — both can cause potassium retention and sometimes hyperkalemia. Two deaths have been reported in patients on such combined therapy (in one, recommended dosage was exceeded; in the other, serum electrolytes were not properly monitored). Observe patients on 'Dyazide' regularly for possible blood dyscrasias, liver damage or other idiosyncratic reactions. Blood dyscrasias have been reported in patients receiving Dyrenium (triamterene, SK&F). Rarely, leukopenia, thrombocytopenia, agranulocytosis, and aplastic anemia have been reported with the thiazides. Watch for signs of impending coma in acutely ill cirrhotics. Thiazides

are reported to cross the placental barrier and appear in breast milk. This may result in fetal or neonatal hyperbilirubinemia, thrombocytopenia, altered carbohydrate metabolism and possibly other adverse reactions that have occurred in the adult. When used during pregnancy or in women who might bear children, weigh potential benefits against possible hazards to fetus.

Precautions: Do periodic serum electrolyte and BUN determinations. Do periodic hematologic studies in cirrhotics with splenomegaly. Antihypertensive effects may be enhanced in postsympathectomy patients. The following may occur: hyperuricemia and gout, reversible nitrogen retention, decreasing alkali reserve with possible metabolic acidosis, hyperglycemia and glycosuria (diabetic insulin requirements may be altered), digitalis intoxication (in hypokalemia). Use cautiously in surgical patients. Concomitant use with antihypertensive agents may result in an additive hypotensive effect.

Adverse Reactions: Muscle cramps, weakness, dizziness, headache, dry mouth; anaphylaxis; rash, urticaria, photosensitivity, purpura, other dermatological conditions; nausea and vomiting (may indicate electrolyte imbalance), diarrhea, constipation, other gastrointestinal disturbances. Rarely, necrotizing vasculitis, paresthesias, icterus, pancreatitis, and xanthopsia have occurred with thiazides alone.

Supplied: Bottles of 100 capsules.

Fifty Years of Medical Practice

PAR FOR LENGTH OF MEDICAL practice is half a century, 50 years. The word "par" is used in the golf sense of a standard of excellence, a mark to shoot at. This year 18 Minnesota physicians complete their fiftieth year of practice in the State of Minnesota, they have been inducted into the 50 Year Club of the Minnesota State Medical Association: their biographies are to be found in this issue*

Fifty years ago focal infection was big in the minds of medical people, and many teeth and tonsils were sacrificed to eradicate this bogeyman. But the most important medical issue of the day was to discover the proper use of the newly released insulin. Russell Wilder of the Mayo Clinic in 1923 in an article entitled "How is the

Overworked General Practitioner to Use Insulin?" anticipating many of his colleagues by half a century stated: "In order to avoid the pitfalls of acidosis on the one hand, and insulin shock on the other, Geyelin has allowed a moderate glycosuria in all his juvenile cases. In the earlier stages of his work, when with others, he was making an effort to maintain a constantly sugar-free urine, he encountered relatively frequent, and sometimes severe, symptoms of insulin overdosage; whereas since his later plan was adopted he has had evidence of insulin shock mildly in only one case. Our experience in the treatment of seventeen children under twelve years of age entirely corroborates that of Geyelin, and we believe with him that, for the time being at least,

*See page 625.

PRECISION X-RAY APPARATUS

it is unwise to attempt to entirely avoid glycosuria. It is much more important to nourish the little patients back to a good weight and strength and to guard them against the danger of acidosis, apparently this may be accomplished very satisfactorily despite a persistent low grade glycosuria."

This and the following quotations are taken from Volume 6 of MINNESOTA MEDICINE, 1923:

Dr. A. W. Abbott speaking before the Minneapolis Surgical Society, said: "After holding the horse and prescribing castor oil for the axles of my preceptor's two-wheeled chaise for a year, and then attending lectures and witnessing operations for six months, I regret to say that, as evidenced by my diploma, I was certified by my teachers as qualified to challenge all human diseases and to welcome newborn innocence to this sinful world. I had my own doubts about this and so had many of the good people on whom I tried it. An internship in a hospital eased my conscience somewhat."

In the same article, Abbott described surgery of a century ago: "Before anesthesia, patients only half asleep with opium disliked long operations. Naturally, the older surgeons had cultivated speed. It saved blood and pain. Come back with me before 1870 to the old operating room in Bellevue Hospital in New York. The operation is to be an amputation of the thigh. The students are sitting around the room, leaving a space about ten feet square for the operation and betting on the probable time the operation would take. The patient is brought in, his night shirt is pulled up out of the way, his legs project from the end of the table, an attendant holds up each stockinged foot. The professor, in dress suit and spotless cuffs, breezes in, the watches of the students come out. (Here I want to assure you that the history of the case, the pathology, the anatomy were clearly and concisely stated.) The tourniquet is applied, an assistant grasps the thigh, the surgeon picks up the long catlin,* he reaches under and over the limb, the time is taken, there is a convulsive shrinking of the patient as the catlin whirls around the thigh reaching the bone in

one sweep, and then, flung to the floor, stands quivering with its point fast in the wood. The retracting bandage is applied, the saw grates through the bone, the attendant drops the leg, the students cheer, the professor bows and the time is in dispute as to twenty-one or twenty-two seconds."

CPC

"On December 6, 1921 I was called to see S.W., aged three and one-half years. The patient had been under our observation for the preceding year as a normal child. At about 4 P.M. the mother reported by telephone from a downtown store that she had noticed the child's lips were blue. Thinking the child might be having a chill we advised the mother to take her home, put her to bed, and keep her warm. This the mother did, but the discoloration had increased to such a degree that the mother became alarmed and called me at 8 P.M.

"The appearance of the child was most striking: the face, mucous membranes, hands and feet were deeply cyanosed, almost black, yet the little patient did not appear distressed and was mentally clear. The temperature was normal. The first impression was that of an acute heart failure. The pulse, however, was of good quality, regular, rate about 140. There was no evidence of enlargement of the heart and auscultation was negative except for a faint, systolic murmur over the base."†

Book Review

"THE FEMALE IMPERSONATORS. Ralph Werter-Jennie June (Earl Lind), 295 pages. Medico-Legal Journal, 1922.

"Our modest author has appointed himself the spokesman and defender of the "third sex." The

*A long straight, sharp, double-edged knife used in amputations (Dorland's).

†F. C. Rodda, a Minneapolis pediatrician published this case report in an article entitled "Nitrobenzol Poisoning in Children." This three and a half year old patient had worn newly dyed, heavy, buckskin shoes the day of her attack and recovered completely in 24 hours.

book is ostensibly a plea for toleration toward homosexualists or bisexualists as the author prefers to term them. The fact that he himself boasts of belonging to this class of mental cripples makes it an open question whether his motive in writing the book is not rather to appease his appetite for admiration and to recall the pleasant memories of his conquests in the character of Ralph-Jennie, the "Faerie" charmer."

— x —

Volume 6 of MINNESOTA MEDICINE in 1923 published many case reports that were presented before various small medical societies. The articles are of particular interest because of the discussions quoted at length with such people as

A. C. Strachauer, Robert Emmett Farr, Arnold Schwyzer, A. W. Adson, F. P. V. Foley and H. B. Sweetser, frequently rising to discuss the papers.

Those of you who are surprised to find the name of one of our golden honorees just out of medical school in 1923, included among discussers should be reminded that the H. B. Sweetser who is quoted is the father of the current H. B. Sweetser.

Most of our 18 golden anniversary honorees are now retired from active medical work. MINNESOTA MEDICINE recognizes their achievements reaching par in medical practice in 1973 and wishes them all well throughout all their future years.

Reuben Berman, M.D.
Editor

Infectious Complications following Legal Abortion

THE ARTICLE by Gaziano and Kaplan* brings to our attention the fact that elective abortion is not an innocuous procedure. Most of the abortions seen in Minnesota during the interval under study were performed elsewhere. Most apparently were performed under ideal medical conditions and, therefore, should have been uncomplicated. As is seen, this was not the case. Since

abortion is likely to be more freely available in Minnesota in the future, centers in which this procedure is to be carried out must be very sure that the liaison with the referring doctor is intact. If there is no referring doctor, a follow-up should be arranged and specific instructions which are fully understood be given to the patient in this regard.

Donlin Long, M.D.

Dr. Donlin Long, associate professor neurosurgery at the University of Minnesota, became professor and head of neurosurgery at Johns Hopkins University, Baltimore, Maryland, July 1.

Dr. Donald Erickson, assistant professor and chief of neurosurgery at St. Paul Ramsey Hospital, became a full-time faculty member at University Hospitals.

Hiatal Hernioplasty—Scleroderma

THE BELSEY MARK IV hiatal hernioplasty has been highly successful in correcting esophageal reflux in patients with hiatal hernia. This repair reduces the gastroesophageal junction to its normal infradiaphragmatic position and plicates the stomach around the distal esophagus.

Lindberg, et al.* report a case of scleroderma with esophageal mobility disturbance and hiatal hernia, repaired by the Belsey Mark IV hiatal hernioplasty. Clinical results, as should be expected, were excellent. The presence of sclero-

derma in a patient with esophageal hiatal hernia is certainly not a contraindication hernia repair and indeed makes repair of this physiologic disturbance even more urgent. Continued esophageal reflux and erosion results eventually in cicatrix and severe esophageal stricture with its attendant morbidity. It is to be hoped that patients with severe and symptomatic esophageal reflux would not be allowed to progress to the state of esophageal cicatrix and stenosis but would be afforded the relief of a more normal gastroesophageal junction.

Fate of the Abandoned Bladder

THE REPORT ON THE fate of the abandoned bladder by Drs. Campbell, DeWeerd and Utz,* citing their experiences with fifty patients over a period of three years is most timely. The apparent increase in the number of patients with neurogenic vesical dysfunction and others for whom the solution of their voiding problem is best provided by urinary diversion has directed attention to complications resulting from the disused bladder. In the series recorded, only four bladders required removal, but none because of pyocystis. In a previous report by the Mayo Clinic group it is noted that ten percent of the patients in their pediatric series required cystectomy because of infection. Another recent series review by Drs. Stewart, Cass and Ireland described their experience with sixty children in whom four of fifteen developed infections in abandoned bladders and required cystectomy. They found the use of .25% silver nitrate solution of value for irrigating of the infected bladders.

Our experience with this problem has been

confined to patients with neurogenic dysfunction, two of whom were children. Six of sixteen required cystectomy because of infection. Several more have had pyocystis treated with lavage and antibiotics to resolution. Removal of the bladder was necessitated not so much by infection as by the dysreflexia which occurred during irrigation, mostly among quadriplegics. The resultant spasms, extreme headaches, hypertension, and severe sweating were unbearable to these patients and all welcomed the relief gained from simple cystectomy. All had had indwelling urethra catheters in place prior to their urinary diversion. Their problems from pyocystis—fever, increased spasms and foul urethral discharge—were not apparent for several months after diversion. We have been impressed by the seeming freedom from symptoms among patients whose bladder outlets were not obstructed, or whose neurogenic disease allowed the bladders to empty the accumulated “bladder mucus” spontaneously.

Philosophical Musings of a Surgeon

Oh, for the good old days when a man could make an honest 20¢ an hour and sleep!—Carl O. Rice, M.D., Ph.D.

Congenital Anomalies of Upper Urinary Tract

MANY PEDIATRIC HOSPITAL admissions are for the evaluation and treatment of urological problems. Anomalies of the bladder and urethra are more common but a significant number involve abnormalities of the upper tract.

Ghosh, Farrow and Furlow in their article, *Congenital Anomalies of the Upper Urinary Tract** have described the developmental anatomy and classified the major abnormalities. Early clinical diagnosis of these abnormalities with the implied prevention of irreversible damage is the responsibility of the pediatrician.

Diagnosis begins with the counting of the umbilical arteries and the observation of the urinary

stream of the newborn. Part of the physical examination of the newborn is palpation of the renal tissue. Evaluation of jaundice, fever, irritability or anorexia of the newborn must include studies of the urinary tract. Infant and children with an unexplained fever should have urine cultures. The urinalysis is an important part of the periodic health examination. Any child with hypertension should have an evaluation of renal arteries.

Some of the anomalies described are incompatible with long life, but the early recognition of many of these can prevent progressive damage to the renal system.

C. Sherman Hoyt, M.D.
Minneapolis, Minnesota

Acute Suppurative Thyroiditis

THE RARE OCCURRENCE of acute suppurative thyroiditis is pointed out by Olin et al.,* in this issue. Reviewing records by discharge diagnosis in two hospitals the writer is associated with, one for five years, one for 10 years, and representing approximately 150,000 patients, failed to reveal one such diagnosis. Although the article includes reports of two cases unrelated except they demonstrated suppurative processes in the thyroid gland, it points up several interesting aspects of infectious thyroid disease.

The relation of the thyroid gland to the oropharynx is supported by its embryologic development from the floor of the pharynx in the area near or at the base of the tongue. The lymphatic drainage of the thyroid relates to the internal jugular chain, pretracheal and retropharyngeal nodes, again indicating its retained relationship to the oropharynx. This may explain suppurative thyroid disease arising from a focus in the oropharynx.

In the pre-antibiotic era, suppurative thyroiditis was somewhat more common and the offending organisms most commonly included streptococci,

staphylococci and pneumococci. Dr. Arnold S. Jackson, in discussing this problem, stated: "... purulent thyroiditis has decreased as empyema and otitis have decreased. I think that in this chemotherapy era we will expect to see less and less purulent thyroiditis."¹ Time seems to have proved his prediction to be true.

In an inflammatory process with associated necrosis the release of thyroid hormone might be expected but does not seem to be a prominent feature of this disease. Of further interest is the apparent suppression of I^{131} uptake reported in the two cases referred to above.

Although the symptoms may be acute and severe, the duration of the process varies from days to several weeks, suggesting that the disease process more appropriately might be called "suppurative thyroiditis" or "thyroid abscess."

It appears that this disease will be seen occasionally and its management should be that related to control the inflammatory process with the use of appropriate bacteriologic studies, antibiotics, and surgery.

Robert D. Blomberg, M.D.
Minneapolis, Minnesota

Femoral Neck Fractures

THIS STUDY* SETS out to show "that prosthetic replacement for acute fractures of the femoral neck has been a satisfactory treatment" at General Hospital. It is recognized, however, by the authors that prosthetic replacement is a procedure of somewhat greater magnitude than internal fixation for an intra-capsular fracture. The mortality rate and the infection rate are thought to be higher although no specific comparison figures are reported here. The infection rate is not quite clear from the data available. There apparently were 16 infections overall and, if based on the 144 acute fractures, it would appear this is in the range of 11 percent.

Selection of prosthetic replacement rather than internal fixation is usually based on the idea that the patient can be ambulated with full weight-bearing more quickly and easily on the prosthesis. No data is presented regarding the average time after surgery that the patients were able to ambulate. This, of course, would have a bearing on the rate of the serious complication of pneumonia, pulmonary emboli, thrombophlebitis, and

perhaps even CVA and myocardial infarction.

The authors state that their present program is to internally fix hip fractures within the first 24 hours regardless of the patient's age and to reserve prostheses for acute fractures with special problems. That this is a reasonable conclusion from this study has to be no more than an impression since no comparison with hip nailing over the same nine-year period is presented. On the other hand, as stated by the authors, prosthetic replacement is a procedure of less magnitude than *total* hip replacement as a treatment for acute fractures in the elderly patient.

A good attempt to grade and analyze function in patients who have had prostheses has been made. It is quite difficult to do so since so much of the hip fracture patient's function depends on factors other than the injury and the surgery. These include age, strength, general health, disposition, and cerebral function.

Overall, the study indicates that prosthetic replacement can be expected to provide pain relief with reasonably good function, but with a relatively high complication rate.

Joseph M. Tambornino, M.D.
Minneapolis, Minnesota

*Moore, R.H. et al.: Femoral Neck Fractures. Analysis of Hip, Prosthetic Replacements, Hennepin County General Hospital, Minnesota Med 56:5:358, 1973

Testicular Tumors

THE MOST DISTRESSING aspect of the diagnosis and treatment of testicular tumors is the fact that so many of these malignancies are not immediately recognized as such by the patient's physician. In a disease where early diagnosis and treatment are the keystones for successful outcome, early referral for urologic evaluation is mandatory for any testicular lesion of whose benign character the physician is not certain.

The question of biopsy of testicular lesions is discussed in detail by Fraley, Markland and Medina.* One would perhaps supplement their discussion by saying that the occasions when one would biopsy a suspicious malignant lesion of the testicle are few and far between. It is probably preferable that diagnosis should be made with

the entire specimen in the surgical pathologist's laboratory when there is a strong clinical suspicion of cancer.

Treatment of testicular tumor requires the services of several disciplines and, as such, after the initial radical orchiectomy, treatment is best handled at a medical center. The precise roles of lymphadenectomy and of chemotherapy in the treatment of non-seminomatous and germinal cell cancer remain to be settled.

Major increases in survival rates for patients with these diseases may come through more effective chemotherapy in concert with lymphadenectomy, but significant improvement can come, now, through early identification by patient and physician.

Joseph W. Segura, M.D.
Mayo Clinic

*See page 593.

Clinical Significance of Antibodies to Polynucleotides

DR. A. L. Fox* has well summarized current opinion about the diagnostic usefulness of antinuclear antibodies. He emphasizes the particular value of testing for antibody to double stranded (ds or native) DNA because this antibody is seldom found in significant titer in diseases other than SLE. The ability to produce this antibody must somehow be related to the pathogenesis of SLE. Whereas under appropriate conditions of immunization it is possible to produce antibodies to single stranded (denatured) DNA in experimental animals, it has not been possible to promote the production of anti double stranded DNA. The only other known disease accompanied by a high frequency of this antibody is the spontaneous renal disease of New Zealand Black (NZB) mice which closely resembles SLE and has been used as an animal model for studying this disease.¹ Antibody to single stranded DNA is of little diagnostic help as Fox points out and could be eliminated from the clinical laboratory without being missed.

Attention has recently been focussed on antinuclear antibodies other than those against DNA and DNP. The term ENA (for "extractable nuclear antigen") was coined by H. R. Holman, G. C. Sharp and their associates to refer to an antigen extractable from nuclei by physiological salt solutions which do not remove DNA.² This material is now known to contain at least two antigens, both responsible for speckled staining of nuclei by the immunofluorescent technique. One of these is a protein first isolated from

nuclei by Tan and Kunkel.³ Antibody to it occurs in up to 50% of patients with SLE. It does not appear to be closely related to the pathogenesis of the disease. Antibody to the other ENA represents antibody to ribonucleoprotein (RNP) since treatment of ENA with ribonuclease destroys its ability to detect this antibody.⁴ It has most commonly been associated with a syndrome characterized by features of scleroderma, polymyositis and SLE. Like other antinuclear antibodies it is not specific for this entity nor is it always present in patients with the clinical picture of the mixed connective disease syndrome. The anti-RNP titers in such patients are usually very high (1:100,000 or so) and do not fluctuate greatly with disease activity. The relationship of anti-RNP to disease is at present only beginning to be explored. Antibodies to double stranded RNA have been identified in the sera of 50% of patients with SLE. Since double stranded RNA does not occur in mammalian cells but is found in certain viruses, especially during multiplication, this finding has been put forward as evidence for the possible role of virus infection in this disease.⁵

Thus, characterization of antinuclear antibodies has provided not only a useful laboratory tool for the classification and management of the connective tissue disease but also a valuable lead for the investigation of the pathogenesis of these perplexing illnesses.

Frederic C. McDuffie, M.D.
Mayo Clinic

Travase® Ointment brand of Sutilains

APPLICATION TECHNIQUE: TRAVASE Ointment is indicated as an adjunct to established methods of wound care for biochemical debridement. It dissolves and facilitates the removal of necrotic tissues and purulent exudates.

TRAVASE enzymes are selective. Virtually inactive on viable tissue.

When this recommended nursing technique is followed without deviation, this procedure can generate visible improvement within 48 hours . . .

(Ulcer being irrigated)
Thoroughly cleanse and irrigate the wound area using only sterile water or sodium chloride solution. Be sure to cleanse the wound of any antiseptics or heavy-metal antibacterial agents which may interfere with the enzyme activity.

Thoroughly soak the wound area. Where practical, tubbing or showering is suitable. Or wet soaks with gauze pads may be used. Remember to avoid chemical cleansing agents which may interfere with the therapy.

With a sterile cotton swab or finger cot, apply a very thin layer of TRAVASE Ointment. The ointment spreads easily and only a small amount is needed (a small dab of ointment will cover an area as big as the back of a hand).

Be sure, though, to rub the ointment well into every crack or crevice of the wound and overlap the surrounding skin one-fourth to one-half inch beyond the area to be debrided—to be sure of complete coverage.

Apply loose, wet dressings, thoroughly soaked in sodium chloride solution or sterile water to the area to be debrided only.

Cover the moist dressings with an occlusive wrap (Saran wrap, Telfa Pads, or other plastic wrappings) to keep wound site moist. Do not extend occlusive wrap over ½ inch beyond area to be debrided.

When changing dressing, gently wipe away the dissolved material. Repeat the complete dressing procedure, including application of TRAVASE Ointment, four times daily.

The ulcer shown in these photos is simulated on a model in order to demonstrate the correct TRAVASE application technique.

_____ Additional Information on TRAVASE® Ointment (brand of Sutilains)

_____ In-service training program

_____ Comment _____

DESCRIPTION: TRAVASE® (brand of sutilains) Ointment is a preparation of proteolytic enzymes, elaborated by *Bacillus subtilis* on a hydrophobic ointment base consisting of 95% white petrolatum and polyethylene. One gram of ointment contains approximately 8 units* of proteolytic activity.

ACTION: TRAVASE Ointment selectively digests necrotic soft tissue, dissolving and facilitating the removal of necrotic tissues and purulent exudates that otherwise impair formation of granulation tissue and delay wound healing (4).

At body temperatures these proteolytic enzymes have optimal activity in the pH range from 6.0 to 6.8.

INDICATIONS: For wound debridement (1,2)—TRAVASE Ointment is indicated as an adjunct to established methods of wound care or biochemical debridement of the following lesions:

- Second and third degree burns,
- Decubitus ulcers,
- Incisional, traumatic, and pyogenic wounds,
- Ulcers secondary to peripheral vascular disease.

CONTRAINDICATIONS: Application of TRAVASE (brand of sutilains) Ointment is contraindicated in the following conditions:

- Wounds communicating with major body cavities,
- Wounds containing exposed major nerves or nervous tissue,
- Fungating neoplastic ulcers,
- Wounds in women of child-bearing potential—because of laboratory evidence of effects of TRAVASE upon the developing fetus.

WARNING: Do not permit TRAVASE Ointment to come into contact with the eyes. In treatment of burns or lesions about the head or face, the ointment inadvertently come into contact with the eyes, it should be immediately rinsed with copious amounts of water, preferably with sterile saline.

PRECAUTIONS: A moist environment is essential to optimal enzyme activity. Enzyme activity may also be impaired by certain antiseptics and detergents (benzalkonium chloride, hexachlorophene, iodine, and nitrofurazone) may render the ointment ineffective to the action of the enzyme (3). Compounds such as containing metallic ions interfere directly with enzyme activity, whereas neomycin, sulfamylon-streptomycin, and do not affect enzyme activity. In cases where adjunctive topical therapy has been used and no dissolution of slough occurs after treatment with TRAVASE Ointment for 24 to 48 hours, further application, but interference by the adjunctive agents, is unlikely to be rewarding.

In cases where there is existent or threatening invasive infection, appropriate systemic antibiotic therapy should be instituted.

Although there have been no reports of systemic allergic reactions in humans, studies have shown that there may be an antibody response in humans to absorbed enzyme material.

ADVERSE REACTIONS: Adverse reactions consist of mild, transient pruritus, bleeding and transient dermatitis. Pain usually controlled by administration of mild analgesics. Side effects are enough to warrant discontinuation of therapy occasionally have been reported.

If bleeding or dermatitis occurs as a result of the application (brand of sutilains) Ointment, therapy should be discontinued. Toxicity has been observed as a result of the topical application of TRAVASE Ointment.

Dosage and Administration

STRICT ADHERENCE TO THE FOLLOWING IS REQUIRED FOR OPTIMAL RESULTS OF TREATMENT

1. Thoroughly Cleanse and Irrigate Wound Area with sterile water or water solutions. Wound MUST be cleansed of all necrotic debris and heavy-metal antibacterials which may denature enzyme substrate characteristics (e.g., Hexachlorophene, Silver Nitrate, Benzalkonium Chloride, Nitrofurazone, etc.).
2. Thoroughly moisten wound area either through tubbing or wet soaks (e.g., sodium chloride or water solution).
3. Apply TRAVASE Ointment in a thin layer assuring it covers all necrotic tissue and complete wound coverage ¼ to ½ inch beyond the area to be debrided.
4. Apply loose wet dressings.
5. Repeat entire procedure 3 to 4 times per day for best results.

How Supplied

3P3002 TRAVASE Ointment is supplied sterile in one-half ounce (14.2 g.) containing 82,000 casein units of sutilain in a hydrophobic ointment base.

The ointment must be stored under refrigeration at 2° to 10° (35° to 50° F).

Fifty Years of Faithful Service

Ann W. Arnold, M.D.

Dr. Arnold is a member of the American College of Surgeons, specialized in obstetrics and gynecology in the Twin Cities area and headed the staff at Asbury Hospital as its President in the 1940's. During her career, she served as Women's Physician at Macalester College in St. Paul, and in 1956, became President and Chief of the Medical Staff of Ripley Memorial Hospital in Minneapolis. Among the obstetrical and gynecological societies of which she was a member are: the Central Association, American College, and the Minnesota State Association.

Born at Mondovi, Wisconsin, Dr. Arnold obtained her B.A. from the University of Wisconsin in 1919 and earned her M.D. at the Medical College of the University of Pennsylvania in 1921. She interned at Philadelphia General Hospital and did her postgraduate work at Woman's Hospital in New York.

Dr. Arnold is the widow of Dr. Duma C. Arnold, a gynecologist, who practiced medicine in Minneapolis until his death in 1950. The Arnolds' son and daughter entered the medical profession, making this an entire family of physicians.

Orwood J. Campbell, M.D.

A surgeon and member extraordinary of the Minnesota State Medical Association, Dr. Campbell was recipient in 1965 of the Distinguished Service Award for his many years of service to medicine in Minnesota. He began his work as a leader in organized medicine when he became Secretary-Treasurer of the Hennepin County Medical Society in 1944, and its President in 1945-46. After election to the Council of the State Association in 1948, he served as one of Minnesota's representatives to the AMA House of Delegates for 16 years, 1951-67.

Born at Sparta, Illinois, Dr. Campbell attended Bradley Polytechnical Institute in Peoria, took his B.S. degree at the University of Chicago, his M.D. at Rush Medical School in 1923, and interned at Presbyterian Hospital in Chicago. He achieved his Ph.D. at the University of Minnesota in 1933 where he was an Associate Professor of Surgery. In addition to an active practice, Dr. Campbell taught at Minneapolis General Hospital and served for a time as Chief of Surgery.

A Founder member of the American Board of Surgery, Fellow of the American College of Surgeons, a member of Western Surgical Society, the Minnesota Surgical Society, and the Minneapolis Academy of Medicine, he retired from practice in Minnesota in 1971.

See editorial, page 615.

FIFTY YEARS

Philip F. Eckman, M.D.

Dr. Eckman is a native Minnesotan, born in Center City. He has practiced general medicine and surgery in Duluth, Minnesota since 1923 and has served as Chief of Staff of each of Duluth's three hospitals.

A graduate of Gustavus Adolphus College, Dr. Eckman received the Greater Gustavus Award in 1965, after serving as trustee and board chairman during the 1950 decade. He graduated from the University of Minnesota College of Medicine and served internships at Ancker Hospital in St. Paul and at St. Mary's in Duluth. He has been a director of the Minnesota Division of the American Cancer Society since 1953 and was that society's president in 1964-65. In 1947, Governor Youngdahl appointed him to the Minnesota Board of Examiners of Nurses, a post he held during the first three years of the L.P.N. program.

Dr. Eckman is a fellow in the American College of Surgeons, a member of the Minnesota Surgical Society, Duluth Surgical Society and the Duluth-Superior Interurban Academy of Medicine.

Malcolm G. Gillespie, M.D.

Certified by the American Board of Surgery and a Fellow of the American College of Surgeons, Dr. Gillespie practiced as a member of the Duluth Clinic surgical staff all during his medical career. He served on the staff of St. Luke's Hospital, was Chief of Staff at St. Mary's, and a consultant at Miller Memorial Hospital.

While active in the St. Louis County Medical Society, Dr. Gillespie held office as secretary-treasurer and as president. He is a Phi Rho Sigma and Alpha Omega Alpha, a member of the Central Surgical Association, and founder-member of the Society for Surgery of the Alimentary Tract.

He obtained his premedical education at Park College, Parkville, Missouri, and the University of North Dakota, and his M.D. at the University of Minnesota.

Born at Minto, North Dakota, Dr. Gillespie is one of three brothers who became physicians and whose families include three sons and one daughter—all physicians.

Benjamin A. Gingold, M.D.

A practicing surgeon and urologist, Dr. Gingold was born in Duluth, Minnesota and acquired his education at the University of Minnesota. He did postgraduate work in surgery for three years on a fellowship at Minneapolis General where he had interned. Upon completing additional studies at Johns Hopkins University in Baltimore, he returned to Minneapolis to become a staff member at Minneapolis General, Asbury Hospital, and, presently, at Mount Sinai Hospital.

Dr. Gingold is an emeritus staff member of Methodist Hospital. He has a life membership in the Hennepin County Medical Society, the Minnesota State Medical Association and the AMA. Dr. Gingold is a member of the American and the International College of Surgery.

Gaius E. Harmon, M.D.

Dr. Harmon maintains an active practice in St. Paul where he has been a lifelong resident. He earned both his B.S. and M.D. degrees at the University of Minnesota and received that school's coveted "M" award in swimming in 1920 and 1921. After two years of internship at Ancker Hospital, Dr. Harmon began his practice as a general surgeon, joining the staff of St. Joseph's Hospital and serving as chief of staff at Midway Hospital.

For four years, he was president of the St. Paul Hearing and Speech Society and is a member of the St. Paul Surgical Society.

Dr. Harmon has been a member of the Minnesota State Medical Association for forty-eight years.

FIFTY YEARS

William W. Heck, M.D.

A general practitioner and graduate of the University of Minnesota Medical School, Dr. Heck began his career as a surgical assistant. Since 1933 he has engaged in solo practice, devoting considerable portions of his time to industrial surgery and medicine. Premedical education was obtained at the College of St. Thomas and he interned at Ancker Hospital in St. Paul. Following a twelve-month rotating internship, Dr. Heck fulfilled a one-year residency in surgery in the same hospital.

He served as chief of staff at both Ancker and St. Joseph's Hospital in St. Paul, was Vice President of the Ramsey County Medical Society, and holds a life membership in the Minnesota State Medical Association.

Louis P. Hiniker, M.D.

Dr. Hiniker practiced in St. Paul during his entire career except for a brief period of time in 1923 which he spent in Belle Plaine, Minnesota. Born in Hastings, he attended the College of St. Thomas in St. Paul for his premed education. He graduated from the University of Minnesota Medical School in 1924 and served his internship at St. Mary's Hospital in Minneapolis.

After the death of his wife in 1932, Dr. Hiniker went on to rear his two children and continue his active practice until 1967 when he retired. He has been a member of the Minnesota State Medical Association for forty-four years.

John E. Holt, M.D.

An internist, with an active practice in St. Paul, Dr. Holt was born in Minneapolis and earned his B.S. and M.D. degrees at the University of Minnesota. He spent his internship at two New York City hospitals, four months at Willard Parker Hospital in the study of contagious diseases, and two years at New York Hospital. Under a Mayo Clinic Teaching Fellowship, Dr. Holt was a resident in medicine at the University Hospital in 1925-26.

He holds the Certificate of Merit as Clinical Assistant Professor of Internal Medicine in the College of Medical Sciences for service to the University and the State of Minnesota in 1925-26 and from 1932 to 1967.

Walter H. Judd, M.D.

After years as a medical missionary in China, Dr. Judd entered politics and won election to Congress in 1942 as a representative from Minnesota's Fifth Congressional District. By popular vote, he returned to Congress for each succeeding term until 1962. Dr. Judd occupies a position of great respect in Washington where he continues to be influential in the nation's affairs. Currently, he is president of the Former Members of Congress Organization.

He is a native son of Nebraska where he graduated from the University of Nebraska Medical School. For 17 months, he interned at the University Hospital in Omaha and did postgraduate work for 27 months at the Mayo Foundation in Rochester.

Dr. Judd has been the recipient of many honors and well-deserved recognition during his colorful, dynamic career. He presently serves as chairman of the Judicial Council of the American Medical Association and is a contributing editor of *Reader's Digest*.

FIFTY YEARS

James W. Kernohan, M.D.

Emeritus staff member at Mayo Clinic, Dr. Kernohan retired in 1962. During his active career, he headed the Experimental and Anatomic Pathology section and was Professor of Pathology for the University of Minnesota Mayo Foundation Graduate School at Rochester.

County Antrim, Ireland, is the birthplace of Dr. Kernohan and his education was obtained at Queen's University of Belfast, North Ireland.

In 1966, that University bestowed upon him the honorary degree of Doctor of Science.

A licensed physician in Minnesota since 1923, Dr. Kernohan became a naturalized citizen of the United States in 1938.

Abraham B. Rosenfield, M.D.

Public health specialist, Dr. Rosenfield joined the staff of the Minnesota Department of Health in 1947 and, within a short time, became Director of the Division of Special Services. That same year, he accepted appointment to the Committee on Obstetrics, Gynecology and Maternal Health (then the Committee on Maternal Health) and played an important role in the development of the Minnesota State Medical Association's unique Maternal Mortality Study Program. He represented the Health Department in the conduct of the program and is still an active committee member.

For many years, he was chairman of the Home Safety Section of the Minnesota Safety Council and continues to serve on the Home Conference Committee of the National Safety Council. Dr. Rosenfield was president of the Minnesota Public Health Association in 1960 and received the Albert J. Chesley Award in Public Health in 1967. From 1967-70 he served as a member of the Minneapolis Board of Public Welfare.

After receiving his M.D. and M.P.H. degrees at the University of Minnesota, he studied for a brief time at Children's Memorial Hospital in Chicago and interned at Minneapolis General Hospital. Dr. Rosenfield practiced at Pequot Lakes from 1924 until 1937, when he accepted the position as School Physician for Hibbing, Minnesota Public Schools.

Benjamin B. Souster, M.D.

Dr. Souster served the Minnesota State Medical Association as secretary for 19 years. In 1958, the Association named him president-elect, and the next year he became president.

A native of St. Paul, he attended Hamline University and obtained his medical training at the University of Minnesota. Upon completing his internship at Ancker Hospital, he became an Assistant in Medicine and a member of the staff there.

Dr. Souster was electrocardiologist and Chief of Staff at Midway Hospital in 1959 and a staff physician at two other St. Paul hospitals, Mounds Park and Miller. During World War I he did his tour of duty with the Minnesota Base Hospital Number 26.

An internist, he was with the Earl Clinic in St. Paul for ten years before establishing his still-active private practice in 1936. Dr. Souster is a Fellow of the American College of Physicians and an Alpha Omega Alpha.

Alf K. Stratte, M.D.

Dr. Stratte practiced medicine in Pine City and gave a total of 28 years of service to the United States as Medical Officer in the Pine City unit of the Minnesota National Guard. He was a two-year veteran of World War I and a five-year veteran of World War II.

A graduate of Carleton College in Northfield and the University of Minnesota Medical School, Dr. Stratte served a rotating internship at St. Francis Hospital in Pittsburgh, Pennsylvania, and at the Northern Pacific Hospital in St. Paul. He holds a life membership in the Minnesota State Medical Association since 1966.

FIFTY YEARS

Horatio B. Sweetser, M.D.

Dr. Sweetser is an internist and member of a distinguished family of doctors. An active member of the Minnesota State Medical Association, he was councilor of the Sixth District from 1953 until 1958 when he assumed the presidency of the Association. As a member of the Association's important liaison committee, he was instrumental in forming the recommendations adopted by the 1963 Legislature which provided for amended licensure for osteopaths in Minnesota.

During his term as president, Dr. Sweetser became well-known as a spokesman for medicine. After four years of service, he left the Navy as a Captain and is a retired University of Minnesota Clinical Associate Professor of Medicine. In 1967, the governor appointed him to the State Board of Health.

A 1921 Harvard graduate and son of a surgeon, he practiced in association with his brother and nephew in Minneapolis for many years.

He has been active in the Minneapolis and Minnesota Societies of Internal Medicine and in the Hennepin County Medical Society. Since 1924, Dr. Sweetser has held most of the important staff positions, particularly at St. Mary's Hospital where, in 1970, he added to his duties, the directorship of the Extended Care Center, a facility he had envisioned and worked to achieve.

Joseph H. Taylor, M.D.

A Minneapolis internist who retired in 1964, Dr. Taylor is a graduate of the University of Michigan Medical School where he was a member of Alpha Omega Alpha and Phi Beta Pi.

He interned at the University of Minnesota Hospitals in Minneapolis, was an affiliate of the Nicollet Clinic and on the staff of three Minneapolis hospitals, Abbot, Eitel, and Northwestern's visiting staff.

Since 1924, he has been a member of the Hennepin County Medical Society and the Minnesota State Medical Association.

Macnider Wetherby, M.D.

A specialist in internal medicine, native of Minneapolis, and graduate of the University of Minnesota Medical School, Dr. Wetherby is a Diplomate of the American Board of Internal Medicine. He interned at St. Mary's Hospital in Duluth and studied on a fellowship at the University of Minnesota where he was an Associate Professor of Medicine, and at the Mayo Clinic in Rochester. As well as serving at the University Hospital, he was a staff member at Asbury Hospital.

Dr. Wetherby has been a member of the Hennepin County Medical Society and the Minnesota State Medical Association since 1927.

Rolland H. Wilson, M.D.

Dr. Wilson was president of the Minnesota State Medical Association in 1956 and a member for 30 years of the Association's House of Delegates. He was an alternate delegate to the AMA in 1957-58 and worked on several of the State Association's committees during his many years of active contribution.

Throughout his long career, Dr. Wilson had maintained an interest in public welfare and was a member of the first Statewide Medical Advisory Committee to the Department of Public Welfare. He served in that capacity for 20 years and headed Winona's Department of Health from 1950 to 1960.

Born in Dakota, Minnesota, the son of a pioneer Minnesota doctor, he spent 34 continuous years of practice in the City of Winona where his son, Louis, was his associate for a number of years.

A graduate of the University of Minnesota Medical School, Dr. Wilson practiced at Harmony, Minnesota, for five years before returning to the University for a year of graduate study in surgery and gynecology. He retired from active practice in 1964.

Letter to the Editor

In reading your piece entitled, "Bones, Backs and Braces" in the May, 1973 issue of MINNESOTA MEDICINE,* I was astounded to note that, "Moe's aggressive therapy for increasing spinal deformity is an example of remarkable change in therapeutic approach." And here we have been deluded into thinking all of these years that all efforts should be directed toward decreasing spinal deformity!

Page 409

Milton Abramson, M.D.
Minneapolis, Minnesota

The Editor replies:

At the risk of attempting to defend the indefensible, I will try to point out to you that it is possible to discuss therapy for pneumonia and one wouldn't assume that the therapy was to produce pneumonia, but rather to relieve it. Thus, therapy for a condition of the back in which the deformity is increasing must be therapy to decrease it. I will write it "Moe's aggressive therapy for: The condition in which spinal deformity is in the natural course of events increasing, but the therapy is going to decrease this increasing spinal deformity and we are going to decrease it aggressively in fact, quite suddenly."

As you see, the expression becomes difficult.

Two Physicians Honored

Dr. Glenn J. Mouritsen and Dr. L. A. Syverson have received commendations for outstanding medical services from the board of trustees and the medical staff of Lake Region Hospital.

Dr. Mouritsen, who has served the hospital's medical staff since 1953, was cited for his time and effort in establishing a program of scientific discussions known as Medical Grand Rounds which he has maintained on a weekly basis for the past four years.

Dr. Syverson, a member of the medical staff since 1958, received recognition for serving as coordinator for the Rural Physicians Program being carried out by the University of Minnesota. He has supervised the program in Fergus Falls for the past two years.

Infectious Diseases

Group B Streptococcal Meningitis in Adults

BARRY J. WOLSTAN, B.A.*

MENINGITIS CAUSED by group B streptococcus is rare. There are only five previously reported cases of group B streptococcal meningitis in adults. These include one case in a diabetic with a skin ulcer.¹ Two cases were postoperative infections,^{2,3} one complicating a laminectomy. The other two cases were associated with brain abscess.⁴ Only one of the previous cases was reported after 1947.

Two cases are reported. The first is unique as group B streptococcal meningitis had not previously been reported as a post-partum sequela in the mother. The second case is similar to one reported in 1965¹ as it involved a diabetic with gangrene of an extremity.

Case Reports

Case 1

A 28-year-old healthy gravida 1 para 1 delivered a normal female infant in a rural Minnesota hospital on January 12, 1971. Her prenatal course and 90 minute labor were uncomplicated. Delivery was spontaneous under transvaginal pudendal block anesthesia. Her post-partum course was uneventful for 45 hours when she developed acute onset of intense headache and photophobia followed in two hours by nuchal rigidity. A lumbar puncture revealed cloudy cerebrospinal fluid with 7400 WBC and a protein of 285 mgm %. Peripheral blood showed 10,700 WBC with 84% neutrophils. She received no drug therapy.

The patient was transferred to the University of Minnesota hospital five hours after the onset of symptoms. Significant physical findings on admission were stupor and a temperature of 103°. Her feet were cold and mottled. Nuchal rigidity was present and she had a positive Kernig's sign. Deep tendon reflexes were hyperactive without clonus. A second lumbar puncture was performed. Emergency treatment included 1 gm. cortisol, 250 cc. plasmanate, and 4 gms. ampicillin, all intravenously.

Spinal fluid examination disclosed 8300 WBC with 96% neutrophils, protein 429 mgm %, and glucose 25 mgm %. A gram stain of the fluid showed a sparse number of gram positive cocci. Blood count was 14,400 WBC with 90% neutrophils. After transfer to the intensive care unit, further intravenous antibiotic therapy was begun with 24 million units penicillin/day and 8 gm. methicillin/day. The patient's temperature dropped to 100° within two hours and she was alert and complaining of headache 12 hours after the institution of therapy.

Culture of the cerebrospinal fluid disclosed non-group A beta hemolytic streptococci, and a precipitin test classified the organism as group B. The blood and urine admission cultures showed no growth and throat culture grew no beta hemolytic streptococci. When the organism had been identified as a streptococcus sensitive to penicillin, methicillin was discontinued. Penicillin was continued at 24 million units/day for seven days at which time the dose was decreased to 12 million units/day. The patient continued to improve. Repeat spinal fluid examination four days after admission showed clear fluid with 170 WBC, glucose 46 mgm %, and protein 56 mgm %. Culture revealed no growth.

Antibiotics were discontinued on the 13th hospital day and the patient was discharged on January 28, 1971, fourteen days after the onset of meningitis. Cultures of the newborn infant were negative as were throat cultures from the patient's husband and other daughter.

Case 2

On February 2, 1971, a 73-year-old comatose Mexican American woman was seen in the emergency room of the University Hospital of San Diego County. She had mild diabetes for 20 years controlled on oral agents. Four weeks prior to admission increasing glycosuria was noted and one week prior to admission she became increasingly disoriented. She had been hospitalized 18 months previously for pulmonary tuberculosis and was treated with INH.

Her temperature was 100.6° rectally. On physical examination she was obtunded but grimaced to painful stimuli. She had bilateral cataracts and a gangrenous left foot. Blood glucose was 625 mgm % and BUN 61 mgm %. Hematocrit was 35% with WBC 8800.

Insulin and fluid therapy were instituted and 10 hours after admission the blood glucose was 455 mgm % and acetone negative. She began to stir in bed. A lumbar

From the Division of Infectious Diseases, Department of Medicine, University of Minnesota Medical School.

*Fourth year medical student. Current address—Department of Ophthalmology, University of Minnesota Medical School.

puncture was unsuccessfully attempted.

Eighteen hours after admission urinalysis showed few WBC and motile bacilli. She was afebrile but treatment with ampicillin was started for a urinary tract infection.

Twenty-four hours after admission the patient was unresponsive and febrile (103° rectally) without localizing signs. A lumbar puncture was performed and showed: 1000 WBC—all PMN's, 100 RBC, gram positive diplococci, glucose 108 mgm % (blood glucose 342 mgm %), protein 290 mgm %. Ampicillin was discontinued and penicillin 20 million units/day intravenously was started.

Blood and CSF cultures revealed group B beta-hemolytic streptococci. The patient responded well to the treatment and her level of consciousness improved. She was eating four days after the institution of therapy. On the eighth hospital day the patient had an amputation below the knee of her left leg. Four days later *E. Coli* was isolated from a transtracheal aspirate. Penicillin was discontinued and kanamycin was given. She had received penicillin for 11 days.

Repeat lumbar puncture on the 13th hospital day showed no cells, protein 24 mgm %, glucose 85 mgm %. Culture was negative. Although the patient's CSF improved and her amputation was healing well, she remained sluggish and *E. Coli* persisted in the sputum. For the next 30 days the patient had recurrent hypoglycemic and hypotensive episodes. Focal seizures were noted. She also developed a holosystolic murmur consistent with mitral regurgitation on the 30th day. She pursued a downhill course with pneumonia and expired on the 48th day.

At autopsy a recent (two to three weeks) massive brain infarct in the distribution of the left middle cerebral artery was found. There was a focal embolic encephalitis and candida and bacteria were seen in the vegetations. Examination of the heart showed a 1 cm. vegetation on the posterior leaflet of a perforated mitral valve.

Discussion

Group B streptococci were originally isolated from cows with mastitis. Various attempts have been made to determine whether the cow is the reservoir for the organism as found in humans, although some investigators believe that the human and bovine strains are serologically distant.

The most common site of isolation in humans is the genito-urinary tract. In a study of 138 human isolates of group B streptococci by Brown,⁵ 46 (30%) were from the vagina, 32 (22%) were from the urine, and 22 (15%) were from the throat.

Cervicovaginal carriers of the organism are estimated at between 3-6%.^{6,7} Almost all of these women are asymptomatic. The most common infection seen is puerperal sepsis, occurring usually after septic abortion or prolonged rupture

of membranes. As opposed to group A streptococcus, pharyngitis caused by group B streptococcus is rare. The organism is highly sensitive to penicillin and is variously resistant to tetracycline and streptomycin.

Meningitis caused by group B streptococcus is a rare occurrence. The reporting of cases in recent years has been increasing because of cases in infants in the perinatal period.

Case 1 is unique because group B streptococcal meningitis occurring as a postpartum sequela in the mother has not to our knowledge been reported before. It is probable that this patient harbored group B streptococcus in her vagina and that following delivery she developed a transient bacteremia with localization to the meninges. A cervical culture was not obtained from this patient.

It is of note that the patient's blood cultures were negative. There is a lack of information on the incidence of positive blood cultures in postpartum and post-abortion sepsis. Reinartz and Sanford⁸ point out that most of the older studies dealt with cervicovaginal cultures.

Case 2 is similar to one reported by Lazarus and associates¹ in that both patients had sepsis of a foot. The primary source of our patient's infection was not found although a positive blood culture was obtained. The gangrenous foot is a possible source although no direct cultures were taken.

The susceptibility of diabetics to infection by group B streptococcus was documented by Eickhoff et al.⁹ In a one year study period, group B streptococci were isolated from 108 patients. Eight of these patients were diabetics with gangrene of an extremity. Six were female and two were male. The organism was isolated from the wound of seven and the blood of the eighth patient. None of the patients had meningitis.

The organisms isolated from these two cases were both sensitive to penicillin and resistant to tetracycline and streptomycin.

Acknowledgments

I am appreciative of the guidance of Dr. Wesley W. Spink, Regents Professor of Medicine at the University of Minnesota Medical School, in the preparation of this paper. I also wish to thank Dr. A. I. Braude, Professor of Medicine and Pathology at the University of California at San Diego for the data on Case 2.

GARAMYCIN Injectable has also been shown
effective in serious staphylococcal infec-
It may be considered in those infections
penicillins or other less potentially toxic
are contraindicated and bacterial
susceptibility testing and clinical judgment
rate its use.

Start with Garamycin

■ Broad gram-negative spectrum

Because of its broad gram-negative spectrum and its
well-established clinical efficacy, GARAMYCIN Injectable
can be considered for initial therapy in suspected as
well as documented gram-negative sepsis.

Stay with Garamycin

■ Susceptibility of causative organisms confirmed

The results of susceptibility tests will, in most cases,
demonstrate the causative organisms' sensitivity to
GARAMYCIN Injectable. However, the decision to
continue therapy with this drug should also be based on
the severity of the infection and the important additional
concepts contained in the Warning Box.

■ Relatively low incidence of adverse reactions

Risk of toxic reactions is low in patients with normal
renal function who do not receive GARAMYCIN Injectable
at higher doses or for longer periods of time than
recommended.

■ Bacterial resistance has not been a problem

In the laboratory, resistance has been demonstrated
to develop slowly in stepwise fashion. No one-step
mutations to high resistance have been reported to date.

Garamycin[®]
gentamicin **injectable**
sulfate

I.M./I.V.

40 mg. per cc.

Each cc. contains
gentamicin sulfate equivalent
to 40 mg. gentamicin

WARNING

Patients treated with GARAMYCIN Injectable should be
under close clinical observation because of the
potential toxicity associated with the use of this drug.
Ototoxicity, both vestibular and auditory, can occur
in patients, primarily those with pre-existing renal
impairment, treated with GARAMYCIN Injectable, usually
for longer periods or with higher doses than
recommended.

GARAMYCIN Injectable is potentially nephrotoxic,
and this should be kept in mind when it is used in
patients with pre-existing renal impairment.
Monitoring of renal and eighth nerve function is
recommended during therapy of patients with known
impairment of renal function. This testing is also
recommended in patients with normal renal function at
the onset of therapy who develop evidence of nitrogen
retention (increasing BUN, NPN, creatinine or oliguria).
Evidence of ototoxicity requires dosage adjustments

or discontinuance of the drug.

In event of overdose or toxic reactions, peritoneal
dialysis or hemodialysis will aid in removal of
gentamicin from the blood.

Serum concentrations should be monitored when
feasible and prolonged concentrations above 12 mcg./
mL. should be avoided.

Concurrent use of other neurotoxic and/or nephro-
toxic drugs, particularly streptomycin, neomycin,
kanamycin, cephaloridine, viomycin, polymyxin B, and
polymyxin E (colistin), should be avoided.

The concurrent use of gentamicin with potent
diuretics should be avoided, since certain diuretics by
themselves may cause ototoxicity. In addition, when
administered intravenously, diuretics may cause a rise
in gentamicin serum level and potentiate neurotoxicity.

USAGE IN PREGNANCY Safety for use in pregnancy
has not been established.

On all in-patient services...
in hospital-acquired gram-negative infections*

Garamycin®

gentamicin sulfate

Injectable

I.M./I.V.

40 mg. per cc.

Each cc. contains
gentamicin sulfate equivalent
to 40 mg. gentamicin

Also available:

GARAMYCIN® Pediatric Injectable, 10 mg. per cc.

GARAMYCIN® Injectable, brand of gentamicin sulfate U.S.P., injection, 40 mg./cc. Each cc. contains gentamicin sulfate equivalent to 40 mg. gentamicin
For Parenteral Administration

WARNING

Patients treated with GARAMYCIN Injectable should be under close clinical observation because of the potential toxicity associated with the use of this drug.

Ototoxicity, both vestibular and auditory, can occur in patients, primarily those with pre-existing renal damage, treated with GARAMYCIN Injectable, usually for longer periods or with higher doses than recommended.

GARAMYCIN Injectable is potentially nephrotoxic, and this should be kept in mind when it is used in patients with pre-existing renal impairment.

Monitoring of renal and eighth nerve function is recommended during therapy of patients with known impairment of renal function. This testing is also recommended in patients with normal renal function at onset of therapy who develop evidence of nitrogen retention (increasing BUN, NPN, creatinine or oliguria). Evidence of ototoxicity requires dosage adjustments or discontinuance of the drug.

In event of overdose or toxic reactions, peritoneal dialysis or hemodialysis will aid in removal of gentamicin from the blood.

Serum concentrations should be monitored when feasible and prolonged concentrations above 12 mcg./ml. should be avoided.

Concurrent use of other neurotoxic and/or nephrotoxic drugs, particularly streptomycin, neomycin, kanamycin, cephaloridine, viomycin, polymyxin B, and polymyxin E (colistin), should be avoided.

The concurrent use of gentamicin with potent diuretics should be avoided, since certain diuretics by themselves may cause ototoxicity. In addition, when administered intravenously, diuretics may cause a rise in gentamicin serum level and potentiate neurotoxicity.

USAGE IN PREGNANCY Safety for use in pregnancy has not been established.

INDICATIONS GARAMYCIN Injectable is indicated, with due regard for relative toxicity of antibiotics, in the treatment of serious infections caused by susceptible strains of the following microorganisms:

Pseudomonas aeruginosa, *Proteus* species (indole-positive and indole-negative), *Escherichia coli* and *Klebsiella-Enterobacter-Serratia* species.

Clinical studies have shown GARAMYCIN Injectable to be effective in septicemia and serious infections of the central nervous system (meningitis), urinary tract, respiratory tract, gastrointestinal tract, skin and soft tissue (including burns).

Bacteriologic tests to determine the causative organisms and their susceptibility to gentamicin should be performed.

Bacterial resistance to gentamicin develops slowly in stepwise fashion; there have been no one-step mutations to high resistance.

In suspected or documented gram-negative sepsis, GARAMYCIN may be considered as initial therapy. The decision to continue therapy with this drug should be based on the results of susceptibility tests, the severity of the infection, and the important additional concepts contained in the Warning Box. In the neonate with suspected sepsis or staphylococcal pneumonia, a penicillin type drug is usually indicated as concomitant antimicrobial therapy.

GARAMYCIN Injectable has been shown to be effective in serious staphylococcal infections. It may be considered in those infections when penicillins or other less potentially toxic drugs are contraindicated and bacterial susceptibility testing and clinical judgment indicate its use.

CONTRAINDICATIONS A history of hypersensitivity to gentamicin is a contraindication to its use.

WARNINGS See Warning Box.

PRECAUTIONS Neuromuscular blockade and respiratory paralysis have been reported in the cat receiving high doses (40 mg./kg.) of gentamicin. The possibility of these phenomena occurring in man should be considered if gentamicin is administered to patients receiving neuromuscular blocking agents such as succinylcholine and tubocurarine.

Treatment with gentamicin may result in overgrowth of nonsusceptible organisms. If this occurs, appropriate therapy is indicated.

ADVERSE REACTIONS

Nephrotoxicity: Adverse renal effects, as demonstrated by rising BUN, NPN, serum creatinine and oliguria, have been reported. They occur more frequently in patients with a history of renal impairment treated with larger than recommended dosage.

Neurotoxicity: Adverse effects on both vestibular and auditory branches of the eighth nerve have been reported in patients on high dosage and/or prolonged therapy. Symptoms include dizziness, vertigo, tinnitus, roaring in the ears and hearing loss.

Numbness, skin tingling, muscle twitching, and convulsions have also been reported.

Note: The risk of toxic reactions is low in patients with normal renal function who do not receive GARAMYCIN Injectable at higher doses or for longer periods of time than recommended.

Other reported adverse reactions, possibly related to gentamicin, include increased serum transaminase (SGOT, SGPT), increased serum bilirubin, transient hepatomegaly, decreased serum calcium; splenomegaly, anemia, increased and decreased reticulocyte counts, granulocytopenia, thrombocytopenia, purpura; fever, rash, itching, urticaria, generalized burning, joint pain, laryngeal edema; nausea, vomiting, headache, increased salivation, lethargy and decreased appetite, weight loss, pulmonary fibrosis, hypotension and hypertension.

DOSAGE AND ADMINISTRATION GARAMYCIN Injectable may be given intramuscularly or intravenously.

For Intramuscular Administration:

PATIENTS WITH NORMAL RENAL FUNCTION*

Adults: The recommended dosage for GARAMYCIN Injectable for patients with serious infections and normal renal function is 3 mg./kg./day, administered in three equal doses every 8 hours.

For patients weighing over 60 kg. (132 lb.), the usual dosage is 80 mg. (2 cc.) three times daily. For patients weighing 60 kg. (132 lb.) or less, the

usual dose is 60 mg. (1.5 cc.) three times daily.

In patients with life-threatening infections, dosages up to 5 mg./kg./day may be administered in three or four equal doses. This dosage should be reduced to 3 mg./kg./day as soon as clinically indicated.

*In children and infants, the newborn, and patients with impaired renal function, dosage must be adjusted in accordance with instructions set forth in the Package Insert.

For Intravenous Administration:

The intravenous administration of GARAMYCIN Injectable is recommended in those circumstances when the intramuscular route is not feasible (e.g., patients in shock, with hematologic disorders, with severe burns, or with reduced muscle mass).

For intravenous administration, in adults, a single dose of GARAMYCIN Injectable may be diluted in 100 or 200 cc. of sterile normal saline or in a sterile solution of dextrose 5% in water; in infants and children, the volume of diluent should be less. The concentration of gentamicin in solution, in both instances should normally not exceed 1 mg./cc. (0.1%). The solution is infused over a period of 1 to 2 hours.

The recommended dose for intravenous administration is identical to that recommended for intramuscular use.

GARAMYCIN Injectable should not be physically pre-mixed with other drugs, but should be administered separately in accordance with the recommended route of administration and dosage schedule.

HOW SUPPLIED GARAMYCIN Injectable, 40 mg. per cc., 2 cc. multiple-dose vials for parenteral administration.

Also available, GARAMYCIN Pediatric Injectable 10 mg. per cc., 2 cc. multiple-dose vials for parenteral administration.

Congenital Anomalies of Upper Urinary Tract

MANAS K. GHOSH, M.D., GEORGE M. FARROW, M.D. AND
WILLIAM L. FURLOW, M.D.

THE GENITOURINARY SYSTEM is formed by the combinations of elements from the undifferentiated mesenchyme, peritoneum, gut, and ectoderm at different stages. In early development, the most important structure is the urogenital ridge, which is formed from the undifferentiated mesenchymal tissue. The first portion of the ridge forms the pronephroi, which join together caudally to form the pronephric duct; the latter persists to unite with the mesonephros, forming the most important structure—the mesonephric duct or the so-called wolffian duct. Pronephroi do not function as such in humans and soon degenerate. The definitive kidney arises in part from the most caudal portion of the urogenital ridge and in part as an outgrowth of the mesonephric duct. A diverticulum grows out of the mesonephric duct, enters the mesoderm of the most caudal portion of the urogenital ridge, and forms the ureter, pelvis, and calices of the kidney. Through subdivision, the major and minor calices are formed. As the kidney develops, its position changes, moving upward from the true pelvis and rotating about 90° medially so that the renal pelvis, which was previously directed ventrally, faces the midline of the body. The bladder and urethra develop from the primitive cloaca.

Incidence of Anomalies

About 10% of all persons have some anomaly of the genitourinary system, and these anomalies account for approximately 30% of all urologic entities. The anomalies vary from minor ones that are rarely responsible for clinical manifestation to major malformations incompatible with extra-uterine life. Some malformations may predispose the kidneys to hypertension, pyelonephritis, or formation of calculi. At least 50% of persons with malformation of the genitourinary system have anomalies of other organ systems.

Congenital Anomalies of Kidney

The congenital malformations of the kidneys

may be described under three main groups: anomalies of the amount of renal tissue (deficient or excessive); anomalies in position, form, or orientation or any combination; and anomalies of differentiation.

Anomalies of Amount of Renal Tissue

Bilateral Renal Agenesis.—More than 200 cases of this anomaly have been reported. Because the condition is incompatible with extra-uterine life, nearly all instances have been found at autopsy—and most in stillborn infants, for only a small

Fig. 1 A—Congenital absence of right kidney. Only adrenal gland is evident.

From the Mayo Clinic and Mayo Foundation, Rochester, Minnesota.

See editorial, page 619.

number live a few days after birth. In about 75% of cases, maternal oligohydramnios or total absence of amniotic fluid is noted. More males than females have renal agenesis (2:1). The facial appearance is rarely normal with this condition. The deformities of the ears, which are low set and deficient in auricular cartilage, are conspicuous. Bilateral pulmonary hypoplasia is an almost consistent finding. The adrenal glands are characteristically ovoid. Bladder, urethra, and gonads are absent in one fifth of cases.

Unilateral Agenesis (Figure 1 A).—There have been about 1,000 cases of this anomaly reported. The left kidney is more frequently absent, and the condition is commoner in males than in females. The homolateral adrenal gland is absent in 5% of cases; the ureter is absent in 50% and is atretic in 25%. In 10% of the cases, the homolateral half of the vesical trigone is absent. Rarely, a single kidney may be ectopic and even more rarely it is crossed. Excretory urograms, cystoscopic examinations, and arteriograms help in the diagnosis.

Congenital Renal Hypoplasia.—This is a rare entity that is often difficult to differentiate from ischemically contracted, atrophic pyelonephrotic, and atrophic hydronephrotic kidneys. The morphologic criteria by which a kidney may be judged truly hypoplastic are poorly outlined. Size of the renal artery is not a true guide because the artery that supplies a secondarily diseased kidney eventually becomes atrophic.

Supernumerary Kidney.—A supernumerary kidney is a mass of renal tissue that has no parenchymatous connection with the definitive kidney. Some duplication of the renal pelvis is present in about 10% of all cases, but a true supernumerary kidney is extremely rare. The excretory urographic demonstration of extra-collecting systems is not enough for the diagnosis of a supernumerary kidney unless the systems are so widely separated that communication between renal masses can be reasonably excluded. Supernumerary kidneys may be as large as the normal organ, but usually they are small and drain through an independent pelvis into the normal ureter on the same side. About two thirds of the supernumerary kidneys are symptomatic, usually because of infection.

Anomalies of Form, Position, or Orientation

Horseshoe kidney, pancake kidney, and disk, sigmoid, and donut kidneys are fused kidneys that

represent anomalies of form.

The horseshoe kidney is the most common anomaly of form. Usually, the fusion is at the lower pole (Figure 1 B), but rarely it can be at the upper pole (Figure 1 C), giving the appearance

Fig. 1 B—Horseshoe kidney, common type in which lower pole is fused. Note abnormal vascular pattern.

Fig. 1 C—Horseshoe kidney, uncommon type in which upper pole is fused.

ance of a horseshoe. The kidney is often low lying, and because of the associated malrotation, the renal pelvis is seen overlying the calices on the excretory urogram; the calices are more in the sagittal than in the oblique plane. The kidney almost always has multiple vascular supplies, which are of important clinical significance when the decision of surgery arises. The incidence of horseshoe kidney varies from one in 400 to one in 1,800.

In fused crossed ectopia, both kidneys are on the same side, being fused to each other, although the ureters enter the bladder in the normal position. The crossed kidney lies below the normal kidney, the latter often being in a low position. There is associated malrotation, and the calices may be club-shaped without being abnormal.

Complete fusion produces the cake or disk kidney. If the upper pole of one kidney fuses to the lower pole of the opposite kidney, a sigmoid kidney is produced (Figure 2 A).

The most common anomaly of position is pelvic kidney, the unascended kidney (Figure 2 B). The kidney can be found anywhere on its normal course of ascent. An unascended kidney is invariably associated with malrotation. However,

this type must be differentiated from the ptotic kidney in which the ureter is of normal length but is kinked because of redundancy. Crossed fused renal ectopia is abnormal not only in form but also in position (Figure 2 C). The crossed unfused renal ectopia is a rare entity. Crossed solitary renal ectopia is a rarer variety and has been mentioned under the heading of renal agenesis.

A thoracic kidney has been reported as an incidental finding on a chest roentgenogram or an excretory urogram. This is another rare entity, more often situated on the left side.

Anomalies of Differentiation, Etc.

Congenital Hydronephrosis.—This anomaly, which is often bilateral, is due to obstruction at the ureteropelvic junction (Figure 2 D). This lesion is the most common cause of an upper abdominal mass in infants and children. Evidently,

Fig. 2 A—Sigmoid kidney.

Fig. 2 B—Normal positioned left kidney and pelvic right kidney. Note malrotation of pelvic kidney, position of renal pelvis, and vascular pattern.

Fig. 2 C—Crossed, fused renal ectopia.

Fig. 2 D—Hydronephrotic left kidney sectioned to show obstructive ureteropelvic function.

the clinical manifestations show up at an early age if the obstruction is severe. If mild, the condition will often escape detection until adult life. An excretory urogram helps in making the diagnosis, and a retrograde pyelogram is often needed when the obstruction is severe. The cause of congenital obstruction of the ureteropelvic junction is not known in most instances, the narrowing being an idiopathic stenosis. In a few cases the ureteropelvic junction may be extrinsically compressed by adjacent anomalous vessels.

Cystic Anomalies of the Kidneys.—Kidney cysts may be either acquired or congenital. Congenital cysts are further subdivided into infantile and adult types. Congenital polycystic kidney have an overall incidence of one in 350 autopsies. The entity has a definite heredofamilial predisposition and often is associated with polycystic conditions of other viscera such as the liver and pancreas. The distinction between the adult and the infantile type is based on the observation that the former has more functioning renal tissue with larger cysts and the latter has multiple uniform small cysts which, on cut surface, give the appearance of a honeycomb. This distinction is of prognostic importance. The kidneys are enlarged in both types of cysts. Most often, polycystic kidneys are bilateral.

A distinct unilateral cystic entity known as multicystic kidney needs to be differentiated from the polycystic kidney. In the former, the appearance of the kidney is lost and is replaced by a mass of thin-walled cysts that have variable size and configuration and are associated with an atretic pelvis and ureter. The multicystic kidneys have no heredofamilial predisposition and are not associated with cystic conditions of other viscera. The artery that supplies the mass is very small and the condition is often associated with aberrant vessels.

Anomalies of the Blood Supply—About 20% of the general population have more than one main renal artery to a kidney. This is more often unilateral than bilateral. Congenital renal arteriovenous malformations are present on arteriographic studies, but such malformations are rare; when this condition is detected in an adult, there is a possibility of a hypernephroma, particularly in a patient who is in the fourth or fifth decade. Other vascular anomalies include congenital renal artery stenosis and idiopathic fibromuscular hyperplasia.

Congenital Anomalies of Pelvis and Ureter*Renal Pelvis and Ureter*

The pelves may vary in number: bifid, trifid, and multifid pelves. These variations are not uncommon and are considered normal, even though they represent a minor error in formation. Differentiation between partial duplication and bifid pelves may be difficult.

Duplication of Pelves and Ureters

Duplication may be partial or complete (Figure 3 A) and unilateral or bilateral. Complete duplication is present when each ureter enters the bladder separately (Figure 3 B) and has a respective ureteral orifice. Incomplete duplication occurs when the ureters of the two pelves unite to form a common ureter before they enter the bladder. The ureter from the lower pelvis, in complete duplication, almost always has the highest and most laterally placed ureteral orifice. Excretory urograms, cystoscopic examinations, and retrograde studies are necessary to diagnose this condition.

Anomalies in Position or Form of the Ureter

Ectopic Ureteral Orifices—This condition is of great clinical importance for two reasons. First, the patient is incontinent if the orifice is distal to the sphincter and second, an opening in the abnormal position is more likely to be obstructed. For the male, the potential sites of an ectopic ureteral orifice are the vesical neck, prostatic urethra, seminal vesicles, vas deferens, and ejaculatory ducts. For the female, the sites are the vesical neck, urethra, vestibule, vagina, cervix, uterus, and fallopian tubes. In either sex, the rectum may be a site. An ectopic orifice is almost always associated with a duplicate system, and the ectopic orifice serves the upper pelvis. An ectopic orifice in a single system is rarely encountered.

Rudimentary Branched Ureter.—Rudimentary branched ureter with a blind ending is a rare anomaly signifying a futile attempt by the ureter to duplicate. A short branching is referred to as a ureteral diverticulum. Most of the ureteral diverticula are acquired from injury, obstruction, or infection.

Retrocaval Ureter (Circumcaval Ureter, Postcaval Ureter).—This was first described in 1893 by Hochstetter as an autopsy finding, and more than 100 cases have been reported in the world literature. The right ureter is almost always involved. One case has been reported from our institution, and in this case, the left ureter was retro-

Fig. 3 A—Complete bilateral duplication.

Fig. 3 B—Closeup of bladder showing independent entries of the four ureters into the bladder.

caval with situs inversus. Retrograde study in association with venacavagraphic findings confirms the diagnosis. The condition needs proper attention when the patient is symptomatic from the

hydronephrotic kidney secondary to obstruction of the affected ureter. The abnormality of the development of the condition primarily lies with the vena cava rather than the ureter.

Case Report

Scleroderma and Esophageal Hiatal Hernioplasty

DAVID E. LANGDON, COLONEL, USAF, MC* AND EVAN F. LINDBERG, M.D.†

MOST PATIENTS with systemic scleroderma have esophageal involvement with absence of peristalsis in the smooth muscle portion of the esophagus, decreased strength of the lower sphincter, and, in many, dilatation due to loss of contractile strength from muscle atrophy. Marked reflux is frequently demonstrable both clinically and radiologically. Hiatus hernias have been commonly associated.^{1,2,3} Intractable esophagitis, ulceration and stricture may result. Such patients are prone to food, especially meat, impactions. In advanced cases there are associated motility problems of the small bowel, colon and stomach. Due to delayed gastric emptying, patients may retire with a full stomach at night even though the evening meal was eaten many hours before with consequent massive protracted nocturnal regurgitation and the potential for broncholaryngeal complications. We routinely institute an antireflux program concomitant with the initial diagnosis of scleroderma. We have had the experience of an early scleroderma patient with normal esophagus by motility and x-ray studies present to us one year later with esophageal ulcer and stricture. The pathophysiology of the sclerodermatous esophagus may simply defeat even the best medical regimen to control reflux.

The successful operative correction of esophageal reflux requires either reconstruction of the esophagogastric closing mechanisms, or the gastric resective procedures, at times including reanastomosis of the GI tract in such a manner as to prevent acid or alkaline esophagitis.⁴ Antireflux operations often include a plication, which in five to 15% of patients with normal peristalsis, results in problems of food passage through the plicated

segment requiring single or multiple dilatations. One would expect profound problems in a patient without peristalsis and decreased muscle contractile strength. The Belsey Mark IV hiatal hernioplasty has been highly successful in correcting esophageal reflux.⁵ This repair includes the artificial reconstruction of the gastro-esophageal junction below the diaphragm by wrapping the fundus of the stomach around the distal 2-3 cm of the esophagus. Logical reservations arise in considering the operative approach regarding consequences of sclerodermatous muscle atrophy, vascular involvement, collagen replacement and adverse effects on healing.

Case Report

A 37-year-old woman consulted her physician in 1965 because of joint pains of the hands. By Xray the joints were normal, but the distal ends of the fingers were noted to be abnormally tapered and scleroderma was suggested as the diagnosis. Skin changes at that time were definite, though mild, involving the face and hands. Raynaud's phenomenon was present. Biopsy confirmed the diagnosis of scleroderma. Intermittent dysphagia began in 1966 which progressed to choking and regurgitation of solid foods in 1968. Between October 1968 and February 1971 there were two documented episodes of aspiration pneumonia. The broncholaryngeal problems were severe with nightly paroxysms of cough, gastric contents regurgitating into the throat and protracted morning cough. These occurred in spite of sleeping on pillows with the bed elevated 12 inches on blocks. Frequently she would have to sit in a chair at night for sleep. She required large doses of codeine to control cough sufficiently to permit intermittent sleep. Pulmonary function tests showed only the progressive development of moderate airway obstructive changes. She was chronically hoarse and laryngoscopy revealed marked inflammatory changes of the larynx, hypopharynx and arytenoid areas. She noted marked regurgitation of food during the day as well and lost approximately 50 pounds in weight. Meat impactions occurred on two occasions responding to proteolytic enzymes and bougienage. Gastrointestinal Xrays confirmed a small hiatus hernia with free reflux of barium into the esophagus. Reflux was confirmed using blue food dye in capsules swallowed at bedtime resulting in deep blue staining of the hypopharynx

*Chief, Gastroenterology Service, Department of Medicine, Wilford Hall, USAF Medical Center, Lackland AFB, Texas.

†Thoracic & Cardiovascular Surgery, 2545 Chicago Avenue, Suite 111, Minneapolis, Minnesota.

See editorial, page 618.

CASE REPORT

and vocal cords. Fiberoptic esophagoscopy revealed moderate esophagitis, a small hiatus hernia associated with a wide open distal esophagus and no visible closing mechanism. No stricture nor ulcerations were noted. Frank reflux of gastric contents into the upper esophagus was evident. An esophageal motility study (Figure 1) confirmed aperistalsis with absence of the distal high

pressure zone at the gastroesophageal junction. After infusion of 0.1 normal HCl into the stomach by tube frank reflux was demonstrated throughout the length of the esophagus by pH electrode. Basal achlorhydria was present on gastric analysis with the pH falling to five after 100 mg of betazole.

The patient conscientiously followed a difficult pro-

Fig. 1—Preoperative esophageal motility study. The tracings confirm the aperistalsis and absence of a distal high pressure zone at the gastroesophageal junction.

Fig. 2—Postoperative esophageal motility study (six weeks). There is an area of increased pressure demonstrated in the region of the gastroesophageal junction.

gram of total medical management with no improvement in her symptoms.

Accordingly, in February 1971, a Belsey Mark IV hiatal hernia repair was performed. At surgery there was a small hiatal hernia defect of the sliding type. A mild inflammatory reaction was present in the distal one-third of the esophagus without ulceration or perforation. The repair was performed as described by Belsey,⁵ bringing the gastro-esophageal junction below the diaphragm without tension. Solid foods were begun on the fourth post-operative day with a mild sensation of sticking in the distal esophagus, persisting until dilatation on the ninth post-operative day (Hurst rubber bougie—size #40). During six months of follow up she sleeps flat in bed and is free of nocturnal and morning cough. Her voice and larynx have returned to normal. She has regained 30 pounds of weight. She has had no difficulty with sticking food, though careful to chew her food well. Esophageal motility study performed six weeks following surgery (Figure 2) revealed an area of increased pressure at the gastro-esophageal junction. Reflux could be demonstrated only during provocative maneuvers. Spontaneous reflux after installation of acid into the stomach was absent.

Discussion

One naturally has grave reservations about surgical intervention in a patient with scleroderma of the esophagus. Payne, et al.⁴ have utilized hemigastrectomy with vagotomy to control acid-peptic secretions, coupling this with an interposition of the small bowel between the gastric remnant and the duodenum to prevent biliary and pancreatic

reflux of the esophagus. At the time of this report, they had experience with two patients with scleroderma of the esophagus, both of whom had severe stenosis and esophagitis with previous attempts at diaphragmatic hiatus hernia repair. These patients have done well following the procedures they described and they noted no difficulty in handling the sclerodermatous tissues.

In the United Kingdom, Belsey has had experience with one case similar to ours.⁶ A Belsey Mark IV hiatal hernioplasty was performed in this patient with satisfactory results during the two year follow-up period.

In our patient, the Belsey repair has had a dramatic impact. She was a hyposecretor and esophagitis had not been a significant problem. During the one year period we have followed this patient postoperatively, there has been no increase in esophageal size and dysphagia has not recurred. This is in spite of progression of her scleroderma in other areas including problems with colonic and small bowel dilatation. The long term performance of an aperistaltic esophagus combined with an antireflux operation remains to be evaluated.

Acknowledgments

We would like to express our appreciation to Lt. Col. John R. Harlan, USAF, MC, for esophageal motility studies and Mrs. Martha Zieber for dedicated secretarial support.

Annual Otolaryngologic Assembly

October 20 through 26, 1973

The Annual Otolaryngologic Assembly of 1973 will be held October 20 through 26, 1973, in the Eye and Ear Infirmary of the University of Illinois Hospital. The Department of Otolaryngology of the Abraham Lincoln School of Medicine, University of Illinois at the Medical Center, offers a condensed basic and clinical program for practicing otolaryngologists under the direction of Emanuel M. Skolnik, M.D., with Burton J. Soboroff, M.D., as co-chairman. This program is designed to bring to specialists current information in medical and surgical otorhinolaryngology.

Interested otolaryngologists should direct their inquiries to the mailing address: Otolaryngology, P.O. Box 6998, Chicago, IL 60680.

G. P. AUSTIN desires an associate. Partner retiring Florida. \$25,000 salary first year. Partnership after one year. 165 bed hospital. Close to Minneapolis and Rochester. Write: Joseph Mlinar, M.D., 605 N. Main, Austin 55912.

COUNTRY LIVING-METROPOLITAN CONVENIENCE—WANTED AND NEEDED: One or two General Practitioners to set up practice in new and equipped clinic with utilities paid and rent free 6-12 months. Service area of 9,000 and rapidly growing. New hospital in planning stages, new high school under construction. Located within one hour of Minneapolis-St. Paul. Dental, Veterinary, and Mental Health Clinics also located here. Golfing, bowling, fishing, hunting, etc. in area. Interview expenses and all moving expenses paid. Join us for comfortable country living with big city benefits. Try it, you'll like it! Write: MINNESOTA MEDICINE—485, 375 Jackson, St. Paul 55101.

INTERNIST wanted to join Six-man Department in twenty-two man multi-specialty group. Growing incorporated practice; nearly new Clinic facilities; full range of fringe benefits, including profit sharing fund participation and generous time-off allowance; equal shareholder at end of one year; salary first year, incentive pay plan thereafter. City of 35,000 with excellent schools and colleges; fine residential areas for family living; 1½ hours to Twin Cities; much recreational and cultural activity available locally. Great place to live and practice. Call collect or write C. H. Brady, Jr., M.D., Mankato Clinic, Ltd., Mankato, Minn. 56001. (Telephone 507-387-1811).

FAMILY PHYSICIAN needed to replace member (taking F. P. Teaching position) of five man F.P. group in Robbinsdale, suburb of Mpls., Minn. Active family practice includes medicine, pediatrics, surgery, and OB, utilizing two nearby hospitals. Salary one year, full partnership thereafter. Contact D. D. Metz, M.D., 3819 W. Broadway, Mpls., Minn. 55422 (612) 533-2534.

SHELL LAKE CLINIC, LTD., Shell Lake, Wisconsin, expanding to seven man group. Three family physicians and one surgeon desire additional two family physicians and one internist. New 70 bed general hospital adjoins clinic. Excellent remuneration in corporate practice. City surrounds one of largest and finest swimming and fishing lakes in Northwest Wisconsin. Call 715-468-2711 or write to Clinic Manager Darrell Bailey.

GENERAL SURGEON AND INTERNIST needed to join expanding 5-man group. Approximately 4,000 patients per month keeps all extremely busy. Located in the heart of the pines and lakes in growing Northern Minnesota community serving area of 35,000. Community features excellent medical facilities, stable diversified economy, year-round recreation and cultural center, and pleasant family environment. Starting salary \$30,000-plus depending on training and experience, all fringes including IRS-approved pension plan. We invite you to call or write us for more information. K. H. Stoler M.D. or T. R. Brill, Administrator, Box L, Grand Rapids, Minnesota 55744; or call 218-326-661 (day) or 218-326-5447 (evenings).

FAMILY PRACTITIONER WANTED to join small progressive group serving beautiful Mille Lacs Lake area, only eighty miles north of Minneapolis. Modern clinic and JCAH seventy-three bed hospital and ECF. Excellent income potential; group support, two out of three weekends off. Away from the madding crowd; yet not too far away. Good schools; clean, uncrowded environment; lakes to live on; unfettered living. We need you. Contact Dr. Dennis R. Jacobson, 612-532-3113 (clinic) 612-532-3628 (home), or Marshall E. Engstrom Hospital Administrator, 612-532-3154 (office) 612-532-3693 (home).

G.P. OR INTERNIST, 40 hour week, no night calls. mainly examining executive and professional people. Easily arranged vacation time or time for varied pursuits. Must be 60 or below, but special provision can be made for orthopedic, cardiac or respiratory impairments. \$30,000 base. Write MINNESOTA MEDICINE—479, 375 Jackson, St. Paul 55101.

PART OR FULL TIME, Southdale or downtown Mpls., GP or internist. Pleasant work, mainly examining executive and professional people, no weekend or evening duty. \$20 per hour part-time or \$30,000 annually full time. Free time easily arranged for outside activities or extra vacations on pro rata income basis. Special arrangements can be made for physical handicaps other than age (62 is the upper limit) or sensory loss. Must be graduate of U.S. school licensed or licensable in Minnesota. Write: MINNESOTA MEDICINE—484, 375 Jackson, St. Paul 55101.

WANTED—Internist—Board qualified or certified for city practice with a group of 2. Good salary. Partnership in future. Write: MINNESOTA MEDICINE—480, 375 Jackson, St. Paul 55101.

Nephrology and the Practitioner*

A Regional Approach to Service and Education

FRED L. SHAPIRO, M.D., F.A.C.P.[†] and RUSSELL KNUTSON, M.D.

NEPHROLOGY is one of the newest and most rapidly developing medical subspecialties. A remarkable increase in knowledge about the pathogenesis, diagnostic techniques, therapy, and prognosis of renal disease, and hypertension has recently occurred. The development and application of renal transplantation and regular hemodialysis to patients with end-stage renal disease have been a strong catalyst to the increased interest in nephrology. Another major factor has been the development of diagnostic procedures useful in studying patients with renal disease and hypertension. These include infusion intravenous urography, isotope scans and renograms, arteriography, clinical renal function tests (creatinine and ¹³¹I iothalamate clearances), assays for renin, aldosterone, parathormone, complement, immunoglobulins, and most importantly, the increased use of closed renal needle biopsy with thin sections, special stains, immunofluorescent, and electron microscopic studies. Although transplantation and dialysis have received considerable publicity in the lay and medical literature, other advances have received less emphasis.

This paper describes an innovative program involving patient services and physician education designed to improve the quality of care being provided to patients with renal disease and hypertension. The program has been developed and is being offered as a service of Hennepin County General Hospital (HCGH) Division of Nephrology.

Background Information

In the past several years many patients with acute and chronic renal failure have been referred to our center at HCGH for evaluation and therapy.

Hennepin County General Hospital, Division of Nephrology, Minneapolis, Minnesota.

*This program is part of the Minneapolis Medical Research Foundation, Inc.

[†]Chief of Nephrology Service, Hennepin County General Hospital and Associate Professor of Medicine, Hennepin County General Hospital and University of Minnesota.

It has been apparent to us that primary physicians are frequently unaware of the recent information about diagnostic procedures, improved therapeutic measures and the possibilities for rehabilitation. There are misconceptions and compromised therapeutic measures being applied because of a lack of current knowledge. Some examples of common practices which may not be the "best" approach include:

1. Forcing fluid to all patients with renal insufficiency. As patients develop preterminal renal failure, they frequently are unable to excrete a large water load. Forcing fluids can jeopardize the patient's life as it may precipitate increasing hypertension, congestive heart failure and pulmonary edema. Urine volume in excess of 2500 cc daily is of no value except in conditions such as chronic nephrolithiasis, multiple myeloma, gout and oxalosis and, in these conditions, fluids may have to be restricted if renal failure develops.

2. Sodium is often restricted when patients have renal disease. Most patients do not require strict sodium restriction. In fact, it is important for the patient to take in as much sodium as his kidneys can excrete to maximize residual renal function. It is a common occurrence for patients to lose large amounts of sodium in the urine and, if not replaced, hypovolemia will result leading to decreased renal blood flow, diminished filtration rate and increasing uremia. Sodium should be restricted only to the level excreted daily by the kidneys, which usually becomes fixed within a relatively narrow range as renal insufficiency progresses.

3. Hypertension is often inadequately treated when renal insufficiency coexists because of fear of worsening the renal insufficiency. Hypertension should be treated and the blood pressure maintained at near normal levels to prevent rapid progression of the renal disease and other complications. As the blood pressure decreases, there

may be a transient rise in the blood urea nitrogen (BUN), but usually creatinine will stabilize or decrease and later the BUN may also decline. Methyldopa and hydralazine are the most useful antihypertensive agents when significant renal insufficiency is present. Diuretics should be used with caution.

4. Furadantin® and Mandelamine® are prescribed for chronic urinary tract infections in patients with renal insufficiency in whom the agents may be ineffective. When the creatinine clearance decreases below 30 cc/min, these agents do not reach significant concentration in the urine. Mandelamine must be in an acid urine (pH under 5.8) to be effective.

5. The diagnosis of chronic urinary tract infection is often made on the basis of chronic pyuria instead of repeated bacteriuria. Chronic pyuria may occur in patients with nephrosclerosis and in any of the several forms of interstitial nephritis in the absence of infection.

6. Some previously controversial areas now have been clarified: the incidence of pyelonephritis and analgesic nephropathy; the use of steroids and immunosuppressive agents in the nephrotic syndrome and various glomerulopathies; the evaluation and treatment of patients with hypertension; selection of patients for dialysis and transplantation; when these therapies are indicated; the prevention of acute renal failure; and the appropriate use of renal biopsies.

There are several reasons why there continues to be disparity between the availability of medical knowledge and its application. The usual approaches to postgraduate education, including medical meetings, postgraduate courses and journal articles, have been relatively ineffective. One of the reasons for this slow dissemination of knowledge is that patients with significant renal disease are relatively uncommon, therefore, most physicians are rarely exposed to the problem. They do not have the benefit of recurrent patient exposure to reinforce learning. Most textbooks on renal disease are either outdated or too technical to be of major assistance to physicians in clinical practice. The current renal literature has been disseminated through various journals making it cumbersome to obtain specific information. Nephrologists primarily involved in fulltime academic activities, including undergraduate and graduate training, research and direct patient

services, have little time to assist physicians in becoming more effective in caring for the patients.

Since the mid 1960's, the Nephrology Division at HCGH has developed a regional treatment program for people with advanced renal disease. The program includes patient evaluation, diagnosis, appropriate medical management, chronic dialysis and renal transplantation as indicated. Dialysis is offered at home, in seven satellite units located in hospitals in Albert Lea, Hibbing, Little Falls and Willmar, Minnesota; Fargo, North Dakota; and in Sioux Falls and Rapid City, South Dakota. There is a large limited care dialysis center in Minneapolis to serve the metropolitan area. The program is coordinated and backed up by the acute dialysis facility and the Nephrology Division at HCGH which comprise the Regional Kidney Disease Center (RKDC)—a nonprofit unendowed foundation. Patients from the region including western Wisconsin, are given a choice as to the type of therapy they will receive and the treatment is performed either in or near their home whenever possible. A few patients who could have benefited from earlier evaluation have been referred to us for treatment of end-stage disease. In some of these patients the end-stage disease may have been preventable, while in others complications could have been averted. Some patients in this region with acute and chronic renal failure, who may have been helped died without being evaluated by a nephrologist.

Evaluation and Training Program

We are attempting to resolve some of the above problems by expanding our established regional program for patients with acute and chronic renal failure into a more comprehensive program for patients with all forms of renal disease and hypertension. We have initiated an inpatient evaluation center at the Metropolitan Medical Center (MMC). Patient services and education are major goals. Our primary responsibility is to provide referring physicians with information regarding management of their patients. Our approach to postgraduate education utilizes recurrent patient contact as the major reinforcement of knowledge acquired by the physician from summaries, explanations and reprints, i.e. a consultation course, provided to him from the evaluation center.

Because of the inadequate physical plant of the current HCGH, the evaluation unit was established at the MMC, the private hospital complex with which the new HCGH is collocating. The facilities at MMC are more conducive to patient comfort and convenience. The patients are admitted to a self-care unit which permits them to take meals in the hospital cafeteria. They are encouraged to remain as active as possible.

The unit is an extension of the HCGH Nephrology Division. The physician staff consists of a Nephrology Fellow, medical house officers and a Nephrology Staff Consultant.

We involve the patient in his own care. He is instructed in monitoring his blood pressure and weight, in what activity level is reasonable for his status and the fundamental aspects of dietary control including defining desired intake of sodium, potassium, fluid, calories and proteins, as well as clarifying the difference between high and low quality proteins. The prognosis as well as the complications of treatment are explained to the patient. When appropriate, specific financial

and vocational counseling is provided by the RKDC staff counselors. For those patients who may require dialysis and/or transplantation, these procedures are explained including the various treatment possibilities, their indications for initiation and the results to be anticipated.

We expect that this type of service provided to referring physicians will assist them in caring for their own patients in the home, reinforcing the patient's confidence in his physician. The physician is provided a continuing educational service. Each patient visit will reinforce information presented in the "consultation course" to the physician.

Early evaluation and long-term observation of patients with renal disease and hypertension are necessary for the development of increased understanding and improved treatment for these patients. Programs such as the evaluation center will make a contribution to the medical community in acquiring and disseminating new knowledge.

It's The Law

Withdrawal of Blood from Corpse for Alcohol Test

A man died in a hospital shortly after suffering injuries in an automobile collision. His body was taken to a funeral home to be repaired for burial. Immediately before beginning the embalming process, the embalmer withdrew a sample of blood from the body and sent it to the coroner's office. The blood sample was subsequently sent to the state police for analysis to determine its alcoholic content. This was all done without the authority, consent and knowledge of the widow.

The widow brought action against the coroner and deputy coroner to recover damages for mental anguish allegedly suffered because of the wrongful postmortem examination.

At the trial, the embalmer testified that he withdrew the blood sample and sent it to the coroner's office at the specific request of the deputy coroner. The coroner and deputy said that the deputy not only acted within his authority but also that he had a lawful duty as a deputy coroner to cause the examination to be made. The court ruled in favor of the coroner, contending that it was his right and duty to perform such indicated examinations.

WAYZATA MEDICAL BUILDING OFFICE SUITES—Located in the fastest growing suburban area in the Twin Cities. We offer:

- Surrounding area of lakes, country clubs, woods, beautiful homes;
- Unsurpassed medical building facilities
- Fast growing area—high median family incomes
- Beautiful building—inside and out
- Inner courtyard with trees and landscaping
- Heated indoor parking
- Adjacent access to freeway system
- Low rental rates—favorable base terms
- Financial services

We have grown to fourteen specialties since our building was completed two years ago. We particularly are interested in Orthopedics, Psychiatry, Urology, Otolaryngology, Internal Medicine and Dentistry. Give us a call. We have a lot more to show you and to talk about. Reply to: Mr. Paske, Wayzata Medical Building, 250 North Central Avenue, Wayzata, Minn. 55391, (612) 473-0031.

GENERAL PRACTITIONER needed as associate in county seat community of 2,000. Modern 35 bed hospital 4 blocks from fully equipped clinic. An excellent opportunity to live the good life in rural Minnesota. Write: Minnesota Medicine-477, 375 Jackson St., St. Paul 55101.

A BETTER PLACE TO PRACTICE MEDICINE. For those who would prefer to live in a warmer climate, avoid the big city school, traffic and practice problems; contact this multi-specialty group, located in a city of 100,000 people in North Central Texas. Specialists in Internal Medicine, Family Practice, Pediatrics, General and Orthopedic Surgery are needed to complement the current staff of twenty-one full time physicians. Wichita Falls Clinic-Hospital, 1300 Eighth, Wichita Falls, Texas 76301.

GENERAL PRACTITIONER desired for northern Minnesota clinic located near Lake of the Woods area. Enjoy the clean air, clear waters, compatible working arrangements including ample time off for meetings, vacations and good financial arrangements. Excellently equipped hospital (acute, skilled nursing and board and care facilities.) fine clinic one block from hospital. Write: Minnesota Medicine, 473, 375 Jackson St., St. Paul 55101.

EMERGENCY DEPARTMENT physician needed to join new Emergency Medical Group providing 24-hour coverage to 350 bed hospital. New Emergency Room Out-Patient Department. Guarantee minimum income. Community of over 100,000—excellent schools, state university, strong economic climate. Year around recreational activities. Contact: Executive Director, Allen Memorial Hospital, 1825 Logan Avenue, Waterloo, Iowa 50703.

EXPANDING TEN MAN FAMILY PRACTICE GROUP in southern Minnesota. Seeks **GENERAL PRACTITIONER OR INTERNIST** for summer of 74. New clinic adjacent to a new 114 bed hospital Fairmont is a progressive community (City of Five Lakes). Starting salary open, early partnership opportunity. Contact D. E. Grandgenett, Fairmont Medical Clinic. 507-238-4263.

WANTED—General Practitioner for an incorporated practice. Wisconsin community of 6,800 on interstate highways. Excellent schools, recreational facilities. Modern clinic adjacent 85 bed hospital. Salary first year then partnership. Call 608-372-4177 Collect.

HELP—us form 3 to 4 man group. 60 bed new hospital. Resident anesthetist, physiotherapist County seat and industrial town. Modern clinic facilities. Supreme fishing-hunting close by. Artificial ice arena. Municipal pool and golf course Shared education and vacation time. Good deal Drs. Delmore and Metcalf, Roseau, Minnesota 56751.

INTERNIST. Wants 40 hour week. Board eligible with multispecialty group or clinic. Will consider part time with hourly rate. Twin cities or vicinity preferred. Start immediately. Write: MINNESOTA MEDICINE—486, 375 Jackson St., St. Paul 55101.

RIVERS EDGE MEDICAL CLINIC—Farmington, Mn. needs two additional General Practitioners to practice in a nearly new Clinic, Hospital and Nursing Home. Fast growing area just 45 minutes from St. Paul-Minneapolis. Metropolitan advantage with Community living. Contact M. H. Hunter, M.D. (612) 463-7181.

Book Reviews

HEMATOLOGY. William J. Williams, Ernest Beutler, Allan J. Erslev and R. Wayne Runales, plus multiple contributors. 1419 pages. McGraw-Hill Book Company, publisher. 1972. Price: \$32.50.

This new textbook of hematology offers those interested in blood disorders a well organized, very complete reference source. It is written in a very straight forward informative manner, and seems well organized on a morphologic basis. There are only occasional color plates, but the quality of those presented are excellent. The black and white figures as well as charts and tables are prevalent, well placed and seem to supplement the text. The book is well indexed, so that material is easily found.

The text is divided into five parts, starting with the basic approach to patients with suspected hematologic diseases, and progresses through the red cell disorders, white cell disorders, coagulation to replacement. Each section is reasonably complete and attempts to answer many common diagnostic and management problems. In addition there is a rather extensive appendix describing various laboratory techniques from special staining to interpretation of erythokinetics.

It appears that this text will emerge as a major contribution to the field of hematology. It can be utilized by those occasionally wishing to review aspects of hematology and those wanting some detailed basic information.

It is hoped that the authors will continue to update the text as necessary and that the high quality exhibited in the first edition will continue. This textbook is recommended to all physicians who have an occasion to utilize information relating to hematology.

Neil R. Hoffman, M.D.
Minneapolis, Minnesota

BABY'S RECIPE BOOK. Linda McDonald. A. S. Barnes & Co., New York. \$8.95.

The high marketability of anything for babies plus the allure of an attractive cover will probably put this overpriced volume in the hands of many mothers. For this reason it is well for the practicing physician to be aware of the contents.

The title is a misnomer. Recipes are included but the text is essentially a manual of nutrition for children from birth through 12 years of age. Much of the material could be condensed without sacrificing either clarity or the easy-to-read format.

The overall concepts presented are good ones. Undoubtedly the author spent considerable time researching the impressive list of articles quoted from professional

sources. It is unfortunate that enough misinformation, inconsistency, and questionable interpretation are found to keep it from being wholeheartedly recommended as a resource for mothers.

Martha Burke-Strickland, M.D.
Minneapolis, Minnesota

SYNOPSIS OF SURGERY, Second Edition. Liechty and Soper. Publication June, 1972. C. V. Mosby Co. \$15.50. 1108 pages. 669 illustrations.

This text is a general review of surgery and the surgical specialties written by Richard D. Liechty, M.D., Associate Professor of Surgery, and Robert T. Soper, MD., Professor of Surgery, and 24 collaborators, all with the exception of three, currently on the faculty of the University of Iowa, College of Medicine, Iowa City, Iowa.

The book is designed as a text for the beginning medical student or a "seasoned physician" who wants a brief review of a surgical topic. All chapters have been updated, and chapters on transplantation, total parenteral feeding and gynecology have been added. References to each chapter are appended at the end of the book, but are not correlated with specific statements in the book.

The usual divisions of organ systems is followed, but chapters on malignant neoplasms, gastrointestinal hemorrhage, intestinal obstruction, pediatric and geriatric surgery are included. Wound healing, fluid and electrolytes, shock, infection and pre- and post-operative care are covered in separate chapters.

In general, the book presents the opinions and methods of the faculty of the University of Iowa. Only one side of controversial subjects is presented, and alternatives are not discussed. This may be well for the reader for whom the book is intended.

The chapter on fluids and electrolytes may be somewhat confusing without supplementary, explanatory descriptions. The chapter on the hand by Furnas and Flatt is exceptionally good and up to the usual standards of Dr. Flatt. Dr. Flock's complete chapter on urology must also be complimented. The illustrations are for the most part good and supplement the text; although occasional pictures tend to show the extreme, unusual manifestation of a particular disease or injury.

The book can be recommended for those for whom it was written as well as for surgeons who want a quick reference or surgical resident preparing for board examinations.

AUGUST 197

Everybody experiences psychic tension.

Most people can handle this tension.

Some people develop excessive psychic tension and need your counseling

and a few may need counseling
and the psychotropic action of Valium® (diazepam).

Before deciding to make Valium (diazepam) part of your treatment plan, check on whether or not the patient is presently taking drugs, and if so, what his response has been. Along with the medical and psychiatric history, this information can help you determine initial dosage, the possibility of side effects and the ultimate prospects of success or failure.

While Valium can be a most helpful adjunct to your counseling, it should be prescribed only as long as excessive psychic tension persists and should be discontinued when you decide it has accomplished its therapeutic task. In general, when dosage guidelines are followed, Valium is well tolerated (see Dosage). For convenience it is available in 2-mg, 5-mg and 10-mg tablets.

Drowsiness, fatigue and ataxia have been the most commonly reported side effects.

Until response is determined, patients receiving Valium should be cautioned against engaging in hazardous occupations requiring complete mental alertness, such as driving or operating machinery.

Before prescribing, please consult complete product information, a summary of which follows:

Indications: Tension and anxiety states; somatic complaints which are concomitants of emotional factors; psychoneurotic states manifested by tension, anxiety, apprehension, fatigue, depressive symptoms or agitation; symptomatic relief of acute agitation, tremor, delirium tremens and hallucinosis due to acute alcohol withdrawal; adjunctively in skeletal muscle spasm due to reflex spasm to local pathology, spasticity caused by upper motor neuron disorders, athetosis, stiff-man syndrome, convulsive disorders (not for sole therapy).

Contraindicated: Known hypersensitivity to the drug. Children under 6 months of age. Acute narrow angle glaucoma; may be used in patients with open angle glaucoma who are receiving appropriate therapy.

Warnings: Not of value in psychotic patients. Caution against hazardous occupations requiring complete mental alertness. When used adjunctively in convulsive disorders, possibility of increase in frequency and/or severity of grand mal seizures may require increased dosage of standard anti-convulsant medication; abrupt withdrawal may be associated with temporary increase in frequency and/or severity of seizures. Advise against simultaneous ingestion of alcohol and other CNS depressants. Withdrawal symptoms (similar to those with barbiturates and alcohol) have occurred following abrupt discontinuance (convulsions, tremor, abdominal and muscle cramps, vomiting and sweating). Keep addiction-prone individuals under careful surveillance because of their predisposition to habituation and dependence. In pregnancy, lactation or women of childbearing age, weigh potential benefit against possible hazard.

Precautions: If combined with other psychotropics or anticonvulsants, consider carefully pharmacology of agents employed; drugs such as phenothiazines, narcotics, barbiturates, MAO inhibitors and other antidepressants may potentiate its action. Usual precautions indicated in patients severely depressed, or with latent depression, or with suicidal tendencies. Observe usual precautions in impaired renal or hepatic function. Limit dosage to smallest effective amount in elderly and debilitated to preclude ataxia or oversedation.

Side Effects: Drowsiness, confusion, diplopia, hypotension, changes in libido, nausea, fatigue, depression, dysarthria, jaundice, skin rash, ataxia, constipation, headache, incontinence, changes in salivation, slurred speech, tremor, vertigo, urinary retention, blurred vision. Paradoxical reactions such as acute hyperexcited states, anxiety, hallucinations, increased muscle spasticity, insomnia, rage, sleep disturbances, stimulation have been reported; should these occur, discontinue drug. Isolated reports of neutropenia, jaundice; periodic blood counts and liver function tests advisable during long-term therapy.

Dosage: Individualize for maximum beneficial effect.

Adults: Tension, anxiety and psychoneurotic states, 2 to 10 mg b.i.d. to q.i.d.; alcoholism, 10 mg t.i.d. or q.i.d. in first 24 hours, then 5 mg t.i.d. or q.i.d. as needed; adjunctively in skeletal muscle spasm, 2 to 10 mg t.i.d. or q.i.d.; adjunctively in convulsive disorders, 2 to 10 mg b.i.d. to q.i.d. *Geriatric or debilitated patients:* 2 to 2½ mg, 1 or 2 times daily initially, increasing as needed and tolerated. (See Precautions.) **Children:** 1 to 2½ mg t.i.d. or q.i.d. initially, increasing as needed and tolerated (not for use under 6 months).

Supplied: Valium® (diazepam) Tablets, 2 mg, 5 mg and 10 mg; bottles of 100 and 500. All strengths also available in Tel-E-Dose® packages of 1000.

The diabetic who has too much... too much sugar, too much fat.

• Maybe the last thing she needs is more of her own insulin. Especially when you consider that many overweight diabetics already have normal or high levels of endogenous insulin and that insulin is lipogenic.

If she just won't diet and oral therapy is indicated in adult-onset, nonketotic diabetes...

DBI-TD[®] Geigy phenformin HCl

lowers blood sugar without raising blood insulin.

For complete details, including dosage, please read the prescribing information. It's summarized below.

phenformin HCl
of 25 mg.
phenformin HCl
disintegration
of 50 and 100 mg.

Indications: Stable adult diabetes mellitus; sulfonylureas, primary and secondary; adjunct to therapy of unstable diabetes mellitus.
Contraindications: Diabetes mellitus that can be controlled by diet alone; juvenile diabetes mellitus; complications of diabetes mellitus (lactic acidosis, coma, infection, gangrene); immediately after surgery where insulin is essential; severe hepatic disease; renal disease with uremia; cardiovascular collapse (shock); disease states associated with hypoxemia.
Warnings: Use during pregnancy is to be avoided.
Precautions: 1. **Starvation Ketosis:** This must be eliminated from "insulin lack" ketosis and is characterized by ketonuria which, in spite of rel-

atively normal blood and urine sugar, may result from excessive phenformin therapy, excessive insulin reduction, or insufficient carbohydrate intake. Adjust insulin dosage, lower phenformin dosage, or supply carbohydrates to alleviate this state. **Do not give insulin without first checking blood and urine sugar.**

2. **Lactic Acidosis:** This drug is not recommended in the presence of azotemia or in any clinical situation that predisposes to sustained hypotension that could lead to lactic acidosis. To differentiate lactic acidosis from ketoacidosis, periodic determinations of ketones in the blood and urine should be made in diabetics previously stabilized on phenformin, or phenformin and insulin, who have become unstable. If electrolyte imbalance is suspected, periodic determinations should also be made of electrolytes, pH, and the lactate-pyruvate ratio. The drug should be withdrawn and insulin, when required, and other corrective measures instituted immediately upon the appearance of any metabolic acidosis.

3. **Hypoglycemia:** Although hypoglycemic reactions are rare when phenformin is used alone, every precaution should be observed during the dosage adjustment period particularly when insulin or a sulfonylurea has been given in combination with phenformin.

Adverse Reactions: Principally gastrointestinal; unpleasant metallic taste, continuing to anorexia, nausea and, less frequently, vomiting and diarrhea. Reduce dosage at first sign of these symptoms. In case of vomiting, the drug should be immediately withdrawn. Although rare, urticaria has been reported, as have gastrointestinal symptoms such as anorexia, nausea and vomiting following excessive alcohol intake. (B) 98-146-103-E (6/72)

For complete details, including dosage, please see full prescribing information.

Pharmaceutical
Association

Maker of Medicine

C. Joseph Stetler
President
Pharmaceutical
Manufacturers
Association

"Too many doctors are indifferent to the economic consequences of their decisions." So stated a recent issue of *Medical News Report* (December 4, 1972), an independent weekly newsletter published by AMA Chief Executive F. J. L. B. game, M.D.

Doctor, are you indifferent...?

In discussing an anticipated increase in Blue Shield rates, Dr. B. ingame's newsletter had this to say:

"In general, it can be said that we have given the impression that we are not particularly concerned with the increase in cost of health care for patients..."

"True, an MD's training is primarily scientific, but in the real world of practice, all of his scientific decisions have a price tag, or an economic impact. The economics of health care beckon the practitioner's attention. Concern for economics of medicine..."

When the pharmacist recommends that a drug product other than the one ordered be dispensed, the prescriber invariably permits the change when he feels the best interests of the patient will be served.

Shortcomings of Pro-Substitution Argument

The fact remains that it is necessary for the prescriber to know when the change is being contemplated, and to be in a position to consent or demur. Without that opportunity, a unilateral decision of the pharmacist made in the absence of clinical knowledge of the patient, could expose him to needless risks, and in addition, jeopardize the relationship between the professions of Pharmacy and Medicine. In my view, there is no offset in the pro-substitution argument that offsets these risks.

The Issue of Drug Knowledge

Substitution advocates claim that the primary justification for changing the rules is the desire to better utilize pharmacists' knowledge about drugs. Yet the pharmacist's task to keep current on the entire field of drug therapy, to some extent, puts him at a disadvantage. More often, a practicing physician with expert knowledge of no more than

ould be an obligation of medical
rvice...

"Medical societies ought to con-
tinuing campaigns to point
he substantial savings that could
alized thru deductible insurance
protection for catastrophic ill-
e. At the very least, they should, in
patients' interest, question the
ices of any insurance organization
raises health care costs by forc-
policyholders to buy insurance
may not need or want and prob-
won't ever use.

"Too many doctors are indiffer-
to the economic consequences of
e decisions. Too many, for ex-
re, habitually hospitalize patients
ne convenience of the MD. It's
ense to deny such habits exist...

"Doctors, thru their medical so-
es, have unhesitatingly appealed
eir patients for support in the
g against government interference
at the private practice of medicine.
n the public in the past has re-
oded. It's time the American Med-
a Association and state and local
elical societies paid off the debt by
esive action to hold down the cost
medical care."

o of Drugs

Insurance rates and hospital
ages are only two factors in health

o drugs that he selects to treat the
arity of conditions encountered in
practice. Moreover, the physi-
as choice of a specific brand is
ed on his knowledge of the pa-
el's medical history and current
ition, and his experiences with
e articular manufacturer's
ruct.

Some substitution proponents
argued that the dispensing of a
cription is a simple two-party
a action between the pharmacist
n the patient, and that a substit-
g pharmacist may avoid even a
chical breach of contract by simply
tlying the patient that he is making
ubstitution. I would judge that
vourts would be sympathetic
toward a pharmacist who substituted
out physician approval and who
nrtook a legal defense that seeks
ake the patient responsible for
e pharmacist's actions.

ected Prescription Prices?

Substitution advocates are
gesting to the consumer, and par-
ticularly the consumer activist, that
ected prescription prices could
lly legalization of substitution.
eave seen absolutely no evidence
t justify this claim. To the contrary,
xperience in Alberta, Canada, where
ubstitution is authorized, suggests

care costs. The cost of drugs—both
prescription and nonprescription—is
another.

And when it comes to drug
costs, the nation's pharmacists are
concerned. Through their national
professional society, the American
Pharmaceutical Association, pharma-
cists are advising the public to use
nonprescription medication cau-
tiously and conservatively, and to seek
the advice of their pharmacist before
selecting or purchasing such drugs.

Outdated Laws

The pharmacist also is aware
that when it comes to prescription
drugs, often he has an even greater
opportunity to reduce the cost to the
patient—with no sacrifice in the qual-
ity of the medication dispensed. But
in many states, outdated and anti-
quated laws prevent the pharmacist
from engaging in drug product selec-
tion. "Drug product selection" simply
means that the pharmacist functions
in the patient's interest by con-
sciously choosing, from the multiple
brands available, a low-cost quality
brand of the specific drug to be dis-
pensed in response to the physician's
prescription order.

Much *misinformation* has been
purposely spread by those who stand
to gain financially by maintaining

the opposite.

Many pharmacists understand-
ably are concerned about the cost of
maintaining multiple stocks of similar
products. While there is no doubt that
inventory costs rise when additional
brands are stocked, it would be inter-
esting to know how much they rise,
and how many pharmacists actually
stock *all* brands—of, say, ampicillin
or tetracycline—or how long they
keep "slow moving" products on their
shelves before they are returned for
credit. To ask that the industry elimi-
nate multiple sources is to ask com-
petitors to stop competing.

Drug Substitution—A License for the Unethical

Anti-substitution repeal would
favor "corner cutting" pharmacists
and manufacturers. For them, free
substitution would be not a right, but
a license. As an aftermath, it is quite
likely that the confidence of both phy-
sicians and patients in the profession
of Pharmacy would be eroded, as
revelations about the unconscionable
behavior of an undisciplined few were
magnified in the press or in profes-
sional circles.

Summary

In short, what the American
Pharmaceutical Association advo-

high drug costs to the public. An end-
less stream of propaganda has ema-
nated from the drug industry in an
effort to persuade the medical profes-
sion that these so-called anti-substitu-
tion laws should be retained. And as
long as these laws are retained, the
drug industry will continue its current
marketing practices which contribute
unnecessarily to high drug costs to
patients. These practices also are in-
viting government agencies to expand
their restrictive controls on physi-
cians and pharmacists.

APhA Efforts

As pharmacists, we are con-
cerned about health care costs. We
hope that every physician shares our
concern on this vital issue, and will
give his personal support to the con-
structive efforts APhA has undertaken
in the interest of all patients.

(For a complete discussion of
drug product selection, you are invited
to request a free copy of the "White
Paper on the Pharmacist's Role in
Product Selection" from: American
Pharmaceutical Association,
2215 Constitution Avenue, N.W.,
Washington, D.C. 20037.)

cates as a broad-spectrum panacea
looks to us to be not only a minority
view (advocacy of substitution is by
no means a uniform policy in Phar-
macy), but also an extraordinarily
costly and ineffective remedy, whose
side effects are odious. We believe
(1) that an impressive majority of
pharmacists prefer to work with
Medicine and with industry, for the
consumer, and for the general good,
(2) that they seek the privilege to sub-
stitute when the patient might gain
and when the patient's doctor agrees,
and (3) that they seek to work for the
resolution of genuine grievances
openly and professionally.

President's Letter

Medical Care for the Poor

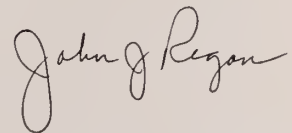

Recent editions of our metropolitan newspapers carried a story quoting a Minnesota political leader who was critical of the method of payment for medical care by several county welfare departments. On almost the same date, the New York Times in an editorial entitled, "To Save Legal Services" criticized the withdrawal of federal funding from the Office of Economic Opportunity's Legal Program for the Poor. It appears that political figures of different persuasions and different levels of government are interested in limiting and possibly even withholding both legal and medical services to the poor. In the opinion of our senator, the various welfare boards could save significant sums of money by paying physicians (and I presume hospitals, pharmacies, nursing homes and other providers) at cost and price levels of 1968. Two important questions were exposed to discussion—first, the inflation which is on our land and on our world. It would be pleasant to be able in 1973 to purchase physicians' services at 1968 levels. Indeed it would be pleasant for any of us to buy food, clothing, shelter or any other item at prices of some past time. The reality of the inexorable rise in costs of all goods and all services makes that simply impossible.

The second question at issue is *who will care for the poor and where will the poor receive care*. It is clear that the poor have already made that decision by abandoning their traditional sources of medical care and turning to the identical resources used by their more affluent fellow citizens. Care of the poor is an old tradition. Greek, Roman and Arabic society provided temples which were hospitals. Medieval society offered hospitals which were really places of refuge for the homeless and helpless. Less ancient history recalls such names as Bethlehem of London which gave a word to our language (bedlam), Hotel Dieu of Paris, the Philadelphia Alms House of the Society of Quakers. Current history included institutions such as Cook County Hospital, Bellevue, and the Charity

Hospital of New Orleans. Many of these places were distinguished for scientific virtuosity often at the expense of personal inhumanity. Many were part of our training years, and poignant memory recalls long lines of waiting poor, sitting with varying patience in innumerable rows of chairs in dark hallways.

I remember the story of a member of my family who while studying in Boston developed a mild respiratory infection. As a student he turned to the outpatient department of what its physician-director called "the world's greatest hospital." His harried tale includes hours in the waiting room, a cursory examination by a disinterested intern, inadequate treatment, all followed by a generous bill. No wonder the poor have turned away from institutional medicine. No wonder the welfare boards have besought the care of private physicians for their clients. The poor are demanding the same care, the same amenities and the same courtesy as the well to do. No longer will there be two standards—the consulting room for the affluent and the clinic for the poor. They have found that in a system of personal rather than institutional responsibility, medical care is not only more available but better.

The day of *liberté, égalité* and *fraternité* is at hand. That great ringing cry of 1789 has come booming down through the years. There is no turning back either in the provision of equal and excellent legal services or in the provision of equal and excellent medical services for all citizens any more than there is a turning back of prices or time to some bygone day.

Fibercolonoscopy

JEFFREY R. LATTS, M.D.,* STUART H. BORKEN, M.D.†
ARNOLD KAPLAN, M.D.‡

FIBEROPTIC ENDOSCOPY of the upper gastrointestinal tract has proved its diagnostic usefulness and has become widely available over the past ten years. Among the more recent advances in fiberoptic instrumentation is the fiberoptic colonoscope which permits direct visualization of the colon well beyond that possible with the conventional proctosigmoidoscope.

Since 1970, an 80 centimeter colonoscope has been in use in the Gastrointestinal Endoscopy Unit at Mount Sinai Hospital in Minneapolis. This paper reviews the results of our first 67 examinations with this relatively new diagnostic technique.

Materials and Methods

The fibercolonoscope is a flexible tube, one centimeter in diameter, which can be introduced through the anus to examine the colon to a distance which varies with the length of the instrument (Figure 1). Light is conducted from a high intensity source through the length of the tube by fiberoptic material. Thus the field of vision is illuminated by cold light. The visual image is likewise transmitted back to the eye of the examiner through a separate fiberoptic bundle.

Channels extending the length of the instrument provide for air insufflation, suction, and introduction of a small stream of water. A separate channel is used to insert a biopsy cable or cytology brush cable for the collection of specimens where appropriate (Figure 2). Photographs can be taken by mounting a 35 mm camera on the eyepiece of the endoscope. The terminal segment of the instrument can be flexed in a 180° arc by rotating a knob at the operating handle in order to direct the instrument around angles and visualize mucosa.

We have been using the Olympus Colonofiberscope, Model CF-SB, an instrument which can be

inserted approximately 80 cm. into the colon. This length is adequate to examine the entire sigmoid colon in all patients and as far as the distal transverse colon in some.

The patient is prepared for the procedure with a purgative the evening before, 10 ozs. of citrate of magnesia, fasted thereafter,

Figure 1

Figure 2

*Intern, Veterans Administration Hospital, Los Angeles, California.

See editorial, page 691.

and tap water enemas until the rectum is clear, the morning of the examination.

Examination is ordinarily performed with the patient in the left lateral decubitus position. Pre-medication is usually not required but in a small number of patients, the intravenous injection of alphaprodine hydrochloride (Nisentil®) or diazepam (Valium®) has been used to relieve abdominal cramping during the procedure.

The tip of the instrument is insinuated gently through the anus. A small amount of air allows easy identification of the lumen and insertion is then continued under direct vision. Negotiation of sharp angles is accomplished by flexing the tip and gently advancing while observing mucosa slipping by. Insertion is accomplished as quickly as possible. Careful observation, photography, and biopsy are performed during withdrawal.

Ambulant patients as well as inpatients referred from other hospitals are included in this report. Ambulant patients were allowed to leave the hospital soon after completion of the examination (with or without biopsy) unless they required medication, in which case they were detained until fully alert.

The 67 patients ranged in age from 18 to 90 years. Thirty-two were men; 44 were inpatients when examined.

Indications for colonoscopy are listed in Table 1. Three of the five patients recorded designated as "other" had a clinical course suggesting colitis but had a normal colon Xray. The two remaining patients were examined through a sigmoid colostomy: One of these to exclude undiscovered polypoid lesions (two unsuspected lesions were discovered at surgery) and one after diversion for apparent diverticulitis.

Results

Diagnostic results are compared with barium enema, the standard, universally accepted tech-

nique. Patients are divided into three groups based on concordance of findings with those of the corresponding barium enema. Group I consists of those patients where there was essential agreement between barium enema and colonoscopy. Group II patients had abnormalities on colon Xray which could not be confirmed endoscopically. Group III is composed of patients whose barium enema study was normal but in whose subsequent colonoscopy demonstrated pathology.

There are 47 patients in Group I. Eleven had normal studies and 36 had abnormalities which were seen both endoscopically and on barium enema examination. Biopsy was performed in several of these patients and the results are included in Table 2. Group I includes all cases of proved carcinoma, as well as two cases of chronic colitis. The remaining abnormalities were all benign polyps.

TABLE 2
BIOPSY RESULTS

Each biopsied lesion is included. Some patients have more than one lesion biopsied.

Adenomatous Polyp	14
Inflammation/Ulceration	18
Villous Tumor	4
Adenocarcinoma	1
Normal Mucosa	6
Ulcerative Colitis	2

The results in Group II patients are summarized in Table 3. Patient one was admitted with mild abdominal complaints and physical examination raised the question of a lower abdominal mass. Barium enema was interpreted as showing a questionable midsigmoid constriction. After the initial examination evaluation, re-examination did not confirm an abdominal mass. The patient was discharged from the hospital and has had no further followup. Patients Two, Five and Six had abnormalities diagnosed on barium enema which could not be confirmed endoscopically. In each case a second colon Xray was normal which supported the endoscopic impression. Cases Three, Four, Seven, Eight and Nine have had no further evaluation and the discrepancy between endoscopic and radiologic findings has not been resolved. Thus, in four of the nine cases in Group II, colonoscopy was of use in excluding suspected pathology and five cases remain unresolved.

There are eleven patients in Group III where colonoscopy revealed abnormalities not seen on barium enema. Four of these were patients with superficial colitis of unclassified type which had

TOTAL		67

TABLE 3
Barium Enema Findings Not Confirmed At Colonoscopy
(Group II)

Patient	Barium Enema	Colonoscopy (numbers in parenthesis refer to length of colon examined, where less than 70 cm.)	Corroborative Evidence
1	Slightly contracted mid sigmoid colon	Several tiny polyps. No constriction.	Resolution of suspected abdominal mass
2	Stricture of sigmoid colon	Normal	Normal repeat Xrays
3	Polyp, distal descending colon	Normal (60 cm.)	None
4	Constriction and possible mass in sigmoid colon	Normal	None
5	Distal sigmoid constriction	Normal	Normal repeat Xrays
6	Colovaginal fistula	Normal (55)	Normal repeat Xrays
7	Sigmoid constriction	Normal	None
8	Descending colon polyp	Normal	None
9	Sigmoid polyp	Normal	None

caused an acute episode of bleeding. Biopsies confirmed the presence of inflammation but were not helpful in classifying the colitis as to type. In two, biopsies and endoscopic appearance were considered diagnostic of ulcerative colitis. One patient was examined following substantial bleeding per rectum. Proctoscopy and barium enema were negative. Subsequently at colonoscopy a small polypoid lesion and a linear ulcer were noted within 10 cm. of the anus. Repeat proctoscopy confirmed these findings.

Forty-nine biopsies were taken in 40 patients. All but 14 of these were obtained from levels above the reach of the proctosigmoidoscope. The results of these biopsies are classified in Table 2. There were eight cases in which the visual impression at endoscopy was carcinoma and biopsy was confirmatory in six.

Seven of these patients had carcinoma at sur-

gery, and the remaining patient, thought to have recurrent carcinoma, had a benign lesion at surgery (endoscopic biopsy was also benign).

There were no serious complications of colonoscopy or biopsy in this series. An occasional patient reported prolonged crampy abdominal pain lasting several hours, probably related to insufflation of a large volume of air. Bleeding from biopsy sites was minimal in all cases.

Comment

The usefulness of endoscopic visualization and manipulation of colon lesions has already been demonstrated by the widespread application of proctosigmoidoscopy. Only the lower 25 centimeters or so of colon has been accessible until recent availability of flexible fiberoptic devices for use in the colon.

Colonoscopy in the patients reported herein, has been a useful diagnostic tool and seems particularly valuable in the evaluation of: (1) Sigmoid constrictions, which may be either inflammatory or neoplastic based on roentgenologic appearance; (2) Inflammatory disease involving the colon above the reach of the proctoscope, where the barium enema may be normal to minimally abnormal and (3) Cases of lower gastrointestinal hemorrhage. Diagnostic accuracy of the small biopsies taken from the surface of polypoid lesions has not been determined but relatively good results have been obtained thus far. Shinya's technique for perendoscopic removal of polypoid lesions seems to be an important advance but has not become widely available as yet.¹

Although colonoscopy has not found the firm place in diagnosis that peroral endoscopy has, it is a promising technique which will undoubtedly find increasing use in disease of the colon especially since the recent development and availability of longer instruments which have a greater degree of controlled tip flexibility.

Drug Fever Caused by Quinine and Quinidine

MICHAEL SCHLUTZ, M.D.*, HORACE H. ZINNEMAN, M.D.* and
WENDELL H. HALL, M.D.*

DURING THE PAST 36 months the Infectious Disease Section of the Minneapolis Veterans Administration Hospital had the opportunity to observe four patients with obscure fever, soon recognized as drug fever, two of them due to quinine and two caused by quinidine. Quinine was administered for a febrile illness, and the recurrence of fever might easily be taken as a sign of ineffectiveness of the drug.

Case Reports

Case 1

A 58-year-old small business owner was referred to Minneapolis Veterans Hospital (MVAH) for evaluation of recurrent episodes of high fever. Thirty years before he had malaria while serving in the Pacific during World War II. One year later he had another attack. He was treated both times uneventfully with quinine and had been without complaints until 1970, when he sustained a myocardial infarction. After three weeks in a hospital he was discharged with prescriptions for digoxin and quinidine sulfate, the latter to be taken whenever he became aware of irregular heart beat. He soon developed alarming episodes of the following constellation of symptoms: Severe cramping of both quadriceps femoris muscles and lower abdominal pain, followed by nausea, vomiting, watery diarrhea and finally chills with fever of 104°F. The episodes subsided after several hours, and occurred at almost monthly intervals for more than one year.

In November 1972 he was referred to MVAH immediately after sustaining a typical attack. He was found to be pale but not in acute distress. His oral temperature was 104°F. The physical examination did not reveal any remarkable findings. The initial laboratory data included a white blood count of 10,700/cu mm, and the differential count showed a shift to the left with 87% neutrophils and 9% stabs. Cultures of blood, urine, pharynx and sputum were normal. Thick and thin blood smears were negative for malaria.

Further questioning revealed that he had been treating an intermittent tachyarrhythmia with digoxin 0.25 mg

and quinidine sulfate 400 mg. He had taken these medications earlier on the day of admission, about two hours prior to the acute attack of his illness, but was unable to correlate previous febrile attacks with this medication.

After three days of well-being he was challenged with 400 mg of quinidine sulfate. Two and one-half hours later he developed shaking chills. His temperature rose to 102.6°F and cramping of the thighs and abdominal pain, watery diarrhea, nausea and vomiting followed soon thereafter. One hour and 45 minutes later the temperature had risen to 105.4°F. Thereafter all symptoms abated and by evening of the challenge day the patient was afebrile.

Case 2

Ten days prior to his admission to MVAH this 44-year-old garage mechanic had suffered vague chest pain followed by rapid, irregular heart action, which persisted to the time of his admission.

The patient was found to be perspiring profusely. Blood pressure was 137/76 mm Hg. Pulse rate was 120/minute and irregularly irregular. The temperature was 98.4°F. There was no exophthalmos nor lid lag, and the visual fields and fundi showed no abnormalities. The thyroid gland was diffusely enlarged. Except for a fine tremor of the extended fingers, other physical findings were unremarkable.

Laboratory findings included normal blood counts and urinalysis. The I^{131} uptake was 46% in 24 hr, the basal metabolic rate was 5% and the protein-bound iodine 5.9 mg/100 ml. The chest roentgenogram demonstrated borderline cardiac enlargement, and an electrocardiogram showed rapid atrial fibrillation and left ventricular preponderance. After digitalization the heart rate slowed to 80/minute and conversion of the atrial fibrillation was attempted with quinidine sulfate, 180 mg being given every two hours for five consecutive doses. On the following day he was given 240 mg of quinidine followed by four doses of 180 mg at two hour intervals. Thereafter he received a maintenance dose of 180 mg of quinidine three times daily. Three days after the beginning of the maintenance dose he developed a fever of 100.4°F, which spiked at times to 106°F.

The fever subsided promptly after cessation of the quinidine. One week later the patient was given a test dose of 180 mg quinidine. Four hours after administration he developed abdominal pain, nausea, vomiting, headache, chills and fever to 102.4°F. All these symptoms disappeared within 48 hours. The patient was discharged in sinus rhythm.

*Department of Medicine, Veterans Administration Hospital, and the University of Minnesota Medical School, Minneapolis.

Reprint requests to Veterans Administration Hospital, 48th Avenue South and 54th Street, Minneapolis, Minnesota 55417. (Dr. Zinneman).

Case 3

A 19-year-old soldier had experienced several chills with fever, nausea and vomiting prior to his return to the United States on an emergency leave. *Plasmodium falciparum* had been found in his blood smear while he was in Vietnam, and treatment with quinine had been initiated. His symptoms did not abate after four weeks of this therapy. Two days after his return to the United States he was referred to MVAH.

Upon admission his temperature was 101°F. His spleen tip was palpable. The physical examination was otherwise unremarkable. Routine laboratory studies, including thick and thin blood smears for malaria, were negative. Quinine therapy, which had been originated in Vietnam, was continued, but the fever persisted with spikes up to 103°F. Blood smears for malaria continued to be negative, and the quinine therapy was stopped on the fourth day. The fever quickly disappeared and the patient remained afebrile for six days. Blood smears continued to be negative for malaria. On the seventh day he was challenged with a single dose of 300 mg of quinine sulfate. Six hours later he developed shaking chills and fever of 104°F. The fever abated within 36 hours and did not return. The patient was discharged without medications and cautioned against the further use of quinine.

Case 4

A 22-year-old soldier was admitted to MVAH two weeks after leaving Vietnam. En route to the United States he complained of sore throat, mild fever, diarrhea, nausea and vomiting. These symptoms remitted after five days, only to recur two days prior to admission with four episodes of fever to 104°F, rigors, profuse diaphoresis, headache and myalgia.

While in Vietnam he had been taking suppressive malaria therapy of chloroquine 500 mg and primaquine 5 mg once weekly and dapsone 500 mg once daily. Oral tetracycline had been administered just prior to his hospitalization. In the remote past penicillin therapy was followed by urticaria. Upon admission his temperature was 102°F. Heart and lungs were unremarkable to percussion and auscultation, and a chest roentgenogram showed no abnormalities. The spleen tip was palpable and mildly tender. The prostate gland was somewhat enlarged, tender and soft. Laboratory data on admission showed normal hemoglobin level, white blood cell count and differential, but only 103,000 platelets per cu mm. Thick and thin blood smears were at first negative for malaria. On the third hospital day trophozoites and gametocytes of *P. falciparum* appeared in the smears, and treatment with quinine (600 mg t.i.d.) and pyrimethamine (25 mg t.i.d.) was begun. Quinine was to be given for a period of two weeks, whereas pyrimethamine was to be administered for three days.

Immediately on the first evening the patient complained of epigastric burning sensation, vomiting and dyspnea. During subsequent days he complained of nausea and weakness following each dose. On the tenth day he was afebrile, and the peripheral white blood cell count showed mild eosinophilia (5%). Quinine was stopped, and the fever disappeared after 24 hours. Malaria smears con-

tinued to be negative, and the patient was discharged with advice concerning quinine sensitivity.

Discussion

The febrile episodes of these four patients occurred at least three days after the initial administration of cinchona alkaloids. Thus, they represent true drug sensitization and not idiosyncrasy, which would manifest itself after the first dose of the alkaloid.

Unlike pharmacologic effects of large doses of these alkaloids,^{1,2} drug fever appears to be associated with the duration of administration rather than the total or daily dose. Fever was the only manifestation of drug sensitization in the two patients who received quinine, whereas the patients to whom quinidine was administered, also had gastrointestinal manifestations. This is by no means a characteristic difference, since quinidine sensitization also has been reported with fever as the only or the most prominent manifestation.^{3,4} The first patient in our report manifested complaints similar to the one patient reported by Siegel et al.⁵

The common features of the four reactions reported here were as follows: Prior use of the drug and/or administration for a duration of a period from three to 30 days, abatement of all symptoms when administration of the drug was stopped, and in three of the patients return of the same manifestations within a few hours of renewed administration of the same medication.

None of our patients developed hemolytic anemia⁶ or thrombocytopenia purpura.⁷ These manifestations have been described repeatedly and are thought to be the consequence of absorption of the alkaloid or its metabolite to erythrocytes or thrombocytes, thus forming an antigenic combination. Hemolytic anemia or thrombocytopenic purpura may then follow in the presence of complement.⁷

Sensitization to quinine does not necessarily imply sensitivity to quinidine. Such a cross-reaction is in the realm of possibility. Dawson's demonstration of cross reactivity of the levo-isomer quinine with cinchonine, which is a dextro-isomer, was observed in a patient with an idiosyncratic reaction rather than an antigenic sensitization.⁸ To date we have little information whether such a cross-sensitization actually exists.

Whether quinine or quinidine are administered alone or in conjunction with other drugs, the awareness of these alkaloids as causes of drug

fever will be helpful, particularly when, as in the treatment of a febrile illness. case of quinine, the medication is given for the

Kleine-Levin Syndrome

This syndrome is characterized by periodic attacks of hypersomnia and abnormal hunger. It was described by Kleine in 1925 and by Levin in 1929 and 1936. The condition has been observed mainly in males 20 to 30 years of age.

The attacks may occur at intervals of a few months with a duration of two to three days or occasionally a few weeks. The patients are apparently normal between attacks. The hypersomnia may appear as a normal or abnormal manifestation. In one reported case, the patient slept like a child during an 11-hour period of continuous bombing of Coventry, England. In other instances the accompanying features may include motor unrest, irritability, gastrointestinal hypermotility, mild mental confusion, incoherent speech, and hallucinations.

The etiology is not known. The syndrome has been reported to occur after acute febrile illness, nonepidemic encephalitis, head injury, and cerebellar tumors. It has been suggested that a lesion within or near the hypothalamus may be responsible, although morbid hunger has also been observed in lesions of the frontal lobe. Glucose and insulin tolerance tests were usually normal, and there was no evidence to suggest the presence of a pancreatic tumor. Electroencephalographic studies were also usually normal, although abnormalities were observed in three cases, one of which revealed the characteristic spiking seen in epilepsy.

Although the syndrome apparently belongs in the narcoleptic group of disorders, it differs from narcolepsy in its characteristic periodicity, the presence of abnormal hunger during attacks, and the absence of cataplexy and disordered nocturnal sleep. Treatment is symptomatic. Cerebral stimulants may be tried for the hypersomnia.

Foramen of Morgagni Hernia

PER WICKSTROM, M.D.* and HOVALD K. HELSETH, M.D.*

MORGAGNI DESCRIBED the hernia which bears his name in 1769.¹ These hernias are now recognized to result from a retrosternal, probably congenital, defect in the attachments of the diaphragm to the sternum and thoracic cage. The point at which the hernia occurs is usually marked by the passage of the superior epigastric artery through the diaphragm. The Morgagni hernia is quite rare. It makes up about three percent of all diaphragmatic hernias. A physician could practice a lifetime and not come across one. The diagnosis is not difficult and, if suspected, the patient can receive prompt surgical correction without undue physical or financial suffering. An illustrative case is presented here as a reminder.

Case Report

A 27-year-old moderately obese woman was admitted to Hennepin County General Hospital in September 1972 with left-sided pleuritic chest pain. On the basis of low PA O₂ and a lung scan which showed a defect in the lingula, the presumptive diagnosis of pulmonary embolism was made and the patient was anticoagulated.

On the admission chest film there was a large mass

at the anterior right cardiophrenic angle (Figures 1A and 1B). Another smaller mass was seen behind the heart in the posterior mediastinum. The posterior mediastinal mass had been noted on a 1968 chest film when the patient was hospitalized for childbirth. At that time it was thought to be benign and had not changed since. The larger, anterior right thoracic mass was not present in 1968.

A barium enema (Figure 2) and an upper gastrointestinal series were done. The barium enema showed the transverse colon to be pulled upward; the upper G.I. was normal. The patient was discharged on anticoagulants with the diagnosis of pulmonary embolism, benign posterior mediastinal mass and probable foramen of Morgagni hernia.

The patient was readmitted after her course of anticoagulants in November 1972 for elective surgery. Through a midline epigastric incision the foramen of Morgagni hernia could be visualized easily (Figure 3). The hernia contents consisted of omentum and this was reduced (Figure 4). The preperitoneal fat also constituted a mediastinal hernia mass and could explain the long standing lower mediastinal mass. There appeared to be both a peritoneal and pleural sac which were ligated and excised. The diaphragmatic fibers were approximated with several interrupted permanent sutures.

The patient was alimenting and ambulating by the second postoperative day and was discharged on the fourth day.

*Department of Surgery, Hennepin County General Hospital, Minneapolis, Minn.

Fig. 1—Preoperative chest film (Left) PA, (Right) Lateral.

Fig. 2—Preoperative barium enema.

Fig. 3—Intraoperative photograph. The omentum pulled up through the foramen of Morgagni (beneath the Richardson retractor).

Her postoperative Xray showed the anterior right cophrenic angle mass to be gone. The posterior mediastinal mass remains (Figures 5A and 5B) but is smaller and its configuration is altered.

Discussion

This case is typical in several respects. The patient is an obese female. Obesity is considered an important precipitating factor,⁴ and seven out of ten people presenting with the Morgagni hernia are women.^{3,4} This patient's hernia presented in the right anterior thorax as is the usual case. She was asymptomatic, as are most.^{5,6} Her hernia was while most likely congenital in etiology, was not detected until adulthood. Morgagni hernias may be seen in the pediatric age group⁶ but most are found after middle age.

Not all Morgagni hernias are without symptoms. Gastrointestinal symptoms such as epigastric distress, fullness, constipation, eructation, and flatulence are mentioned. Respiratory symptoms, such as cough and shortness of breath, are also reported in some patients.^{3,4} The colon is usually included in the hernia contents, but symptoms of bowel obstruction are rare. Abdominal organs most com-

Fig. 4—Intraoperative photograph. The omentum reduced. The upper retractor is in the foramen of Morgagni.

Fig. 5—Postoperative chest film. (Left) PA, (Right) Lateral.

only found in Morgagni hernias, as listed in increasing frequency by Comer and Clagett,³ include omentum, colon, stomach, liver and small bowel.

The key to the diagnosis is the chest film which reveals a right-sided smooth, anterior hemithoracic mass. Left-sided hernias and bilateral hernias occur but are unusual.^{2,3} The differential diagnosis includes such conditions as pericardial cysts, pleural cysts, mesothelioma, lipoma, lymphoma, teratoma, thymoma, and bronchogenic carcinoma. Barium enema proves helpful since the hernia often contains transverse colon as reported by

Comer and Clagett in 30 of their 50 patients.³ When it does not, an upward deformity of the transverse colon might be noted, as in the case presented here. Other studies which have been recommended are the upper gastrointestinal series and pneumoperitoneum.^{5,6}

If the diagnosis can be made with some certainty, the repair can be accomplished through a small epigastric incision. If not, the right chest might be explored and the repair done from above. The former approach is not only easier for the surgeon but also for the patient, in terms of postoperative morbidity and length of hospital stay.

Leukapheresis in the Management of Chronic Leukemia

I. E. FORTUNY, M.D.*, L. CRANDALL, M.D.†, J. McCULLOUGH‡, A. THEOLOGIDES, M.D.# and B. J. KENNEDY, M.D.§

THE ONSET OF chronic leukemia may be insidious and prolonged asymptomatic periods occur. The occurrence of symptoms appears to depend upon the extent of the total accumulated white blood cell mass. Especially in chronic lymphatic leukemia, long periods of observation have been made of asymptomatic disease without therapy.

In chronic myelogenous leukemia cyclic oscillations of granulocytes and platelets have been demonstrated in some patients prior to and during chemotherapy.^{2,8} These cycles have been observed for years (Figure 1, Phase I) until cell removal mechanisms begin to fall behind the cell production rate (Figure 1, Phase II). As cells accumulate in the normal granulocyte pool (bone marrow, spleen and liver), the cell removal mechanism becomes ineffective, and Phase III of the disease is entered (Figure 1). Studies of this phenomenon offer the possibility of further understanding the leukemic process and introduction of new concepts of therapy.

It was postulated that mechanical removal of white blood cells by leukapheresis would permit the recovery of an effective cell removal mechanism, with a resulting symptom free physiologic steady state. The effect of repeated leukapheresis in 12 patients with chronic lymphocytic leukemia, reported by Curtes,⁶ documented objective evidence of regression of disease in 10 of the 12 patients. These investigators considered leukapheresis a potentially useful treatment with chronic

lymphocytic leukemia. Vallejos, studying 10 previously untreated patients with chronic myelogenous leukemia reported reduction in spleen size and peripheral leukocyte counts of greater than 50% in a majority of patients following leukapheresis. In view of these findings, further study of the effect of leukapheresis in chronic leukemia utilizing the blood cell separator was indicated.

Methods and Materials

The Aminco Celltrifuge[™] is operated at the Masonic Memorial Cancer Hospital by the Section of Medical Oncology in cooperation with the Blood Bank of the University Hospitals. The apparatus provides the opportunity to remove specific blood cell components from patients or normal donors. The procedure is described elsewhere.¹

Patients with chronic leukemia were selected for study by leukapheresis because of the presence of high volumes of white blood cells. Inform-

consent was obtained from the patients as human volunteers. Ambulatory patients were managed on an outpatient basis.

Results

Chronic Lymphatic Leukemia

A 61-year-old physician with chronic lymphatic leukemia, after five years of management with chemotherapy became refractory to treatment. Because of increasing leukocytosis, total body irradiation was given every two months over the next two years with moderate control of symptoms but not of the leukocytosis. Because of increasing hepatomegaly, lymphadenopathy and leukocytosis of 700,000 per cmm, all indicating progressive accumulation of lymphocytes, removal of lymphocytes from the body sanctuaries was considered feasible by leukapheresis.

During a series of 21 leukapheresis procedures over 72 days, there was a reduction of the white blood cell count from over 700,000 to around 100,000 per cmm (Figure 2). The platelets increased, the liver decreased in size, but the enlarged lymph nodes remained unchanged. The patient experienced significant symptomatic improvement.

Chronic Myelogenous Leukemia

The effect of leukapheresis was studied in five patients with chronic myelogenous leukemia.

Case 1

A 15-year-old girl had been found to have periodic cycles of leukocytosis while she was followed for 2½ years without treatment (Figure 1). After 18 months, when the leukocyte count failed to return to baseline levels during each cycle, tiredness, fatigue and splenomegaly became more pronounced. These signs and symptoms were

Fig. 2—Leukapheresis in a male with chronic lymphatic leukemia refractory to chemotherapy and radiotherapy.

the result of progressive accumulation of the white blood cell mass. Leukapheresis was begun and the peripheral leukocyte count was reduced to a level below 20,000 cells per mm^3 (Figure 3). Twelve leukapheresis procedures performed over an eight week period resulted in removal of over 190 billion leukocytes. Subsequently, there was a rise in the hemoglobin and maintenance of the leukocyte count in the 20,000-40,000 range for 10 months after leukapheresis, without chemotherapy. However, in the 11th month, the spleen became palpable and the nadir of the granulocyte counts surpassed 60,000 cells/ mm^3 (Figure 3).⁸ Leukapheresis was again carried out decreasing the leukocyte count to the previous low levels. The patient has remained well for eight months, more than 22 months since her first leukapheresis.

Fig. 3—(Case 1). Leukapheresis in cyclic leukocytosis of chronic myelogenous leukemia.

Case 2

A 64-year-old man was followed without treatment for 1.5 years and a definite cycling of the white blood cell count was observed (Figure 4). When the white blood cell count exceeded 100,000 per mm^3 fatigue, tiredness and splenomegaly were noted. The use of leukapheresis was undertaken. He was withdrawn from study after only two leukapheresis procedures because of a traumatic injury at home resulting in a subdural hemorrhage that contraindicated the further use of leukapheresis.

Fig. 4—(Case 2). Cyclic leukocytosis in untreated chronic myelogenous leukemia.

Case 3

In a 26-year-old woman symptoms due to massive splenomegaly prevented study of the cyclic phenomenon of leukocytes and immediate treatment was required. Leukapheresis was carried out five times weekly for eight weeks in an attempt to reduce the stores of leukocytes. Although there was a temporary reduction of the spleen size, a rebound in the peripheral white blood cell count occurred with a rapid increase in the size of the spleen. Hence, leukapheresis was discontinued.

Case 4

A 53-year-old woman had been successfully managed with hydroxyurea therapy for nearly two years. Because of escape from this therapy, leukapheresis was initiated. After nine procedures, fever, painful massive splenomegaly, and leukocytosis continued. The program was discontinued.

Case 5

A 38-year-old woman with anemia and massive splenomegaly due to chronic myelogenous leukemia was submitted to leukapheresis. Two courses of hydrea, 80 mg per kg per day, were given to decrease the leukocytosis and thrombocytosis. After 34 procedures the abnormal hematologic parameters improved, however there was no reduction in spleen size (Figure 5). Therefore the leukapheresis was discontinued and maintenance chemotherapy using hydrea was begun.

Fig. 5—(Case 5). Leukapheresis in non-cyclic chronic myelogenous leukemia.

Discussion

The cell separator apparatus provides an unusual opportunity to study chronic leukemia by removal of large stores of leukocytes in a short period of time. Preliminary reports by Freireich and his associates^{6,7} suggested promising potential for the management of chronic leukemia by this method. Careful evaluation of their data shows that complete remissions did not occur.

Our observations in six patients were varied depending on the extent of the disease. The results of leukapheresis suggested that in the symptomatic stage (Phase III), only a partial, temporary improvement to Phase II can be induced, failing to return the patient to a physiologically steady state (Phase I). The changes in Case 1, suggest that leukapheresis in the earlier phases of the disease might well induce a physiologically steady state.

Leukapheresis in the management of chronic myelogenous leukemia suggests that leukocytosis is not unrelenting, provided the cell removal mechanisms are effective. Mechanical aid in cell removal may provide a useful means to decrease white cell mass which the normal removal mechanisms are no longer able to dispose of. By decreasing the over-expanded pool of granulocytes mechanically, cycling may be allowed to continue (Phase I) a sign of adequate physiologic control, therefore postponing the need for the use of chemotherapeutic agents.

Cell kinetic studies before, during, and after leukapheresis will undoubtedly shed further information regarding the basic defect in the pathogenesis of chronic myelogenous leukemia. Although leukapheresis is an experimental procedure, it could prove to be the initial approach in the long term management of chronic leukemia, by aiding the granulocyte removal mechanisms to effectively dispose of the load as they appear to do in Phase I of the disease.

Combined Therapeutic Approach

ALAN H. ROSENBAUM, M.D.* and RICHARD M. STEINHILBER, M.D.*

THE MANAGEMENT of patients with psychosomatic (pseudophysiological) disorders is often difficult. As many papers have emphasized, the diagnosis of such disorders is not easy;¹⁻⁴ but diagnosis can be made easier by identifying certain characteristics of patients who tend to somatize their emotional conflicts.^{3,5,6} Treatment also may be a problem. Although treatment is more successful than it used to be—these patients once remained physical cripples—still treatment often fails. Attention to ways of improving the diagnosis and treatment of patients with psychosomatic disorders is therefore important.

We report four case histories to illustrate the difficulties in diagnosing and treating patients who have psychosomatic disorders and organic disease with psychogenic overlay. These case reports further illustrate some of the underlying psychodynamics and the need these patients have for their symptoms. But most importantly, they emphasize the importance of unity between referring doctor and psychiatrist in providing the patient the best opportunity for successful treatment. Although the problems are primarily those of back pain, we recommend the same approach be used for most pseudophysiological disorders.

Report of Cases

Case 1

A 37-year-old woman was evaluated for low back pain and for possible use of a body cast. Her pain had begun three years before admission. Myelography then revealed a protruding disk, and six months later she consented to laminectomy and fusion. Her symptoms then abated. One year prior to admission she was in an automobile accident and immediately her symptoms recurred. Roentgenographic studies showed that the fusion was intact and the result of myelography was normal. The patient quit her job and became almost totally disabled. She became addicted to drugs and was admitted to our psychiatric unit because of this. Two psychiatrists thought

the patient to be an emotionally stable person who became addicted because of physical pain. An orthopedic consultant confirmed the previous findings and recommended no further surgery; he also told the patient that a body cast would not help. Confronted with the fact that her pain had a psychogenic as well as organic basis and that she had to live with it, the patient chose to accept psychotherapy together with physical therapy.

The patient's history indicated a life-long pattern of turmoil. Her parents had separated when she was young. Her mother was an abusive alcoholic and, at her mother's behest, the patient assumed the maternal role. She married to escape her mother's household. She did not feel sexually adequate and her husband reinforced this. She had had one affair and was tempted toward another, but back pain kept her from having the affair and also prevented her from having relations with her husband. This was the primary gain or her way of diminishing the anxiety of the intrapsychic conflict (her temptation as opposed to her moral standards). Her background made her susceptible to the conflicts to which she eventually succumbed. Not having the strength (that is, adequacy of self-image and the ability to deal with her desires and hostility) to cope with these conflicts, she chose a physical symptom, which had to some degree an organic basis.

After eight weeks the patient returned home. She was taking no drugs and was able to get a job and resume her household activities. She separated from her husband. She was doing well when seen six months later.

Case 2

A 59-year-old woman had a seven-year history of severe low back pain and of many surgical procedures, including three lumbar fusions and a percutaneous cordotomy. These did not relieve the pain. Eight months prior to admission she was treated with analgesics in the hospital for six weeks. Two months later her pain again worsened so that she was unable to function, and required oxycodone compound (as Percodan) and pentazocine (Talwin). Two weeks before admission, a physical examination indicated that there was no further need for any surgical procedure. The patient was transferred to the open psychiatric unit where she insisted for 10 days that nothing was wrong. During the final confrontation, she tried to look at some of her home life and it became obvious that her marriage was unhappy. Her back pain had begun some 30 years earlier, when she fell down the stairs while six months pregnant. This occurred

*Mayo Clinic and Mayo Foundation, Rochester, Minnesota.

shortly after her husband had fondled a woman while the three of them were lying in bed together. The patient's back pain was her way of avoiding her rage at her husband and further kept him from getting near her. This pain became more severe as further conflicts arose.

Her symptoms subsided to a point where she began walking and stopped taking analgesics. She was transferred to the Intensive Psychotherapy Center, which she attended with her husband. Marital counseling ensued.

Case 3

A 53-year-old woman had a history of persistent back and neck pain of 20 months' duration. Pain had begun after her automobile had been hit by an unattended car that rolled into the street. The neck pain began three days later, initially in the posterior cervical area, and radiated to the left shoulder, posterior arm, forearm, and fourth and fifth fingers. There was numbness and weakness of the left hand. Several days later pain began to radiate from the low back region to the lateral parts of the thighs. No neurologic deficit was elicited. The pain, both in the neck and back, was treated conservatively. One month later a myelogram showed evidence of disk protrusion at the C-6 and C-7 interspace. The disk was excised and a cervical fusion was done. This operation did not relieve the pain, which in fact intensified. Six months later, reevaluation provided no evidence of any neurologic defect; findings included an intact cervical fusion, and a lumbar pseudospondylolisthesis of L-4 and L-5 due to degenerative changes of the lumbar vertebrae. The orthopedist recommended physical therapy and psychotherapy but also told her she would need a lumbar fusion within the next year.

The patient was admitted to the open psychiatric unit for two weeks. Her history elicited the following: She came from a broken home. Language problems made her early schooling difficult and financial problems prevented her attending college. Her husband had had a myocardial infarct seven years earlier and became an invalid; she had to take over all of his duties. One year before her admission, the husband had undergone a coronary bypass procedure and was able to go back to work. She was seen by a psychiatrist at that time for anxiety and depression; her symptoms abated following this initial consultation. Soon after the car accident occurred she became almost totally incapacitated. While in the hospital, however, she insisted she had no feelings about her husband's illness, nor about the stress placed on her by her son—a "genius" who practiced the piano until 4:00 a.m. and had her type his papers until late at night. She said that her doctor had stated that surgery was necessary and that it would relieve her symptoms (partly this reflected her misinterpretation and partly the message he conveyed) and that she had nothing to talk about.

The patient's symptoms were her way of dealing with her rage at her husband and family. She could not consciously justify her anger since she knew that her husband's illness was real; furthermore, realizing that she herself had been deprived of a chance to achieve academic success, she wanted her son to succeed. Simultaneously she was again deprived of the normal dependency needs related to marriage—as she had been while

a child; the deprivation rekindled the pent up anger from the past. She was not able to express these feelings as a child and still lacked the necessary expressive tools to deal with them as an adult.

Neurologic and orthopedic reevaluation was done six months after discharge, and she was then dismissed with the diagnosis of functional back pain.

Case 4

A 36-year-old man had had numerous somatic complaints for two years before we evaluated him. His symptoms began when he fell and injured the lower part of his back. Three days later, he noticed pain in the costo-vertebral angle and hematuria. The hematuria cleared up but one month later the low back pain necessitated treatment in the hospital with bed rest and traction. He was unable to work following discharge. A myelogram, two months later, was followed by surgical exploration of his spine. No protrusion of the disk was found. The postoperative course was complicated by foot drop and associated paresthesias and, four days after operation, by sweating and tachycardia on sitting. A month later, tachycardia occurred every morning also; he was afraid to leave the house. During that month he lost 11.3 kg (25 lb) in weight. Methylprednisolone (as Depo-Medrol) was given two months later. Pain in both legs then developed and he complained also of alternating urinary retention and polyuria. He was treated with thioridazine (Mellaril) but then complained of edema of both legs and of impotence. Six months later, while driving, he noticed the onset of amblyopia and tachycardia. He was again hospitalized. While in the hospital a urinary tract infection developed, with temperature of 39.4 C (103 F); he received antibiotics and diazepam (Valium). After a further six months all medications were stopped; his symptoms recurred, with priapism early in the mornings in addition. Investigations included a glucose tolerance test, which was normal. A psychiatric consultation was requested. The patient stated that the psychiatrist found nothing wrong with him.

He sought another evaluation six months later. He was told that he did have permanent L-5 nerve root damage. Despite this, his symptoms and total incapacity were considered to be excessive in relation to his physical disability. He was transferred to the psychiatric ward.

His interviews disclosed a most difficult childhood. When a child he had been sent to a military school in Austria. He was forced to do military duty; this culminated in his spending 14 months in a prison camp, in which he saw many people die and he himself had little to eat. On being released at the age of 14, he was reunited with his family; he found them starving. His father insisted on his finishing school. After he completed school his father then demanded that he enter a seminary—which he did for six months before quitting. He emigrated to Canada at age 20 while his father was home dying of cancer. Within four years, he had received two masters' degrees. He then worked to achieve a position which made him responsible for 12,000 people. In this capacity he was required to dismiss people from their jobs and felt extremely guilty in doing so. His superior was demanding and to get his work done he often had to work for as long as 20 hours each day. Just

prior to his initial injury, he had been passed over for a promised higher position.

His symptoms were his way of expressing his anger and disappointment over his not being recognized for his work and accomplishments. They rekindled a mixture of feelings he had had toward his father, whose demands on him were excessive but for whom he cared and whom he wanted to please. Further added to this was the anger at his physician (an authority figure) who had operated on him and left him with a foot drop. Moreover his work resulted in his firing many people which rekindled the guilt acquired in prison camp (being allowed to live while others died and his family starved).

While in the hospital he made some progress but each time a test was done, his psychologic condition would regress to the extent of his denying any feelings about what had happened to him and all his symptoms would recur. And when the organic tests had been completed, he returned to a condition characterized by the emotional conflicts that had troubled him. His progress was difficult; repressed hostility, disappointment, and guilt emerged. But after two months of intensive therapy he became able to alter his ways of expressing his feelings enough that he was able to return home and to his job.

Discussion

Although the nature of our practice is such that we see many patients with psychosomatic disorders, our role—as it should be for all physicians—is to examine the whole patient as well as to exclude the possibility of organic disease. Then it is necessary to tell patients with or without organic disease that they cannot benefit from further physical treatment.

It is difficult to tell a patient that he has more pain than a physical examination can justify and that further physical treatment is not indicated. Similarly, we are aware that physical treatment of psychogenic pain can give a patient complete relief when the patient's underlying conflict is resolved and he no longer needs his symptom.

The difficulty in confronting somatizing patients lies in the physician's desire to help the patient by treating his pain, and the patient's need to keep the pain which he communicates to the doctor. Furthermore, patients are now more sophisticated and their psychosomatic symptoms more subtle, which makes the physician worry about the possibility of an occult lesion.

As our cases illustrate, when pain was treated physically it remained unaltered or became worse, or a different symptom occurred. The use of narcotic analgesics conveys the message signifying that pain must be of an organic nature. Further,

these analgesics are often used by the patient as an escape into a dream world. When given by injection the pain often fulfills the patient's masochistic need. All the patients clung to their symptoms rather than face their emotional problems. In Case 3, the patient never got to her conflicts as she heard only that she was to have surgery in the future and was sure that this would solve her pain problem. In Case 4, the patient developed numerous symptoms, would grasp onto whichever one was being investigated, and at those times would deny any conflicts.

Even if a patient has had physical symptoms of psychogenic origin for many years, he may still benefit from psychiatric treatment. But, psychiatric treatment cannot be carried out until a physician closes all avenues of physical treatment, thus forcing a patient to face the underlying conflicts.

One approach to such patients would be to tell them that they do have pain and that it is understood that the pain is real. They can be told that emotions can cause pain or intensify the pain of organic lesions and that it would be best to *try* to explore the possibility of their emotions playing a role in the origin of their pain. This approach is face-saving to patients and allows them to keep their symptoms until their conflicts can be unraveled and new ways can be developed, through psychotherapy, to help them deal with their emotions in a more constructive manner.

Psychosomatic disorders are difficult to treat. A major reason for this is lack of communication between the referring doctor and the psychiatrist. The patient often interprets this lack of communication as a lack of agreement in the diagnosis and this fulfills the patient's basic need to deny emotional conflicts and keep his symptoms. Many psychiatrists have little experience in this area and often choose to wait until all physical treatments have been exhausted. This often leads to an unfortunate situation for the patient. Our experience suggests that it is imperative that psychiatrists and their medical and surgical colleagues work together for the best approach to the patient with a psychosomatic disorder. The treatment must seem to the patient to be the result of a medical team working with him for his good. Then the patient can join the therapeutic team in his treatment and have a chance for improvement.

Post Nephrectomy Arteriovenous Fistula

WILLIAM DeWOLF, M.D.*

POST SURGICAL ARTERIOVENOUS fistulas are being reported with increasing frequency. The first, described by Hunter in 1762¹ involved the brachial vessels following blood letting. Since that time there have been many reports of fistulae, resulting from many types of surgical procedures.²⁻⁸ However an arteriovenous fistula of the renal artery and vein following nephrectomy is an uncommon complication. The English literature lists 21 cases.[†] We describe herein a patient of unusual interest who developed bacteremia from an infected post nephrectomy arteriovenous fistula.

Case Report

A forty-two year old white man was admitted from another hospital with chills, fever of 104°F and positive blood cultures for staphylococcus, coagulase positive. In 1951 he had undergone a left nephrectomy for hydronephrosis due to ureteropelvic junction obstruction. The operative report indicated that the procedure was performed without difficulty and the vessels were tied individually. He had a blood pressure of 125/60 and a continuous bruit over the left flank. Blood chemistries were normal. A chest Xray revealed an enlarged heart and infiltrates suggestive of septic emboli. A diagnosis of post nephrectomy arteriovenous fistula with bacterial endarteritis was made. The patient was treated with intravenous sodium nafcillin for two weeks (6 grams per day) and his fever receded quickly. A midstream aortogram was performed which demonstrated a large left renal artery-renal vein fistula with immediate filling of the inferior vena cava (Figure). Cardiac catheterization was then performed and revealed a cardiac output of 10.3 liters per minute (about twice normal). The arteriovenous fistula was excised. The fistula measured 2-3 mm in diameter and carried a blood flow of 1200 ml per minute, about 11 percent of the patient's cardiac output. The postoperative course was uneventful. He is well, six months after surgery.

Discussion

The 21 reported post nephrectomy arteriovenous fistulas have been diagnosed as early as

five months and as late as 35 years after nephrectomy. Indications for nephrectomy included tuberculosis, carcinoma, stones and hydronephrosis. A bruit over the involved flank is characteristic. In addition, they may have findings suggestive of a high cardiac output state including the widened pulse pressure, cardiomegaly, and even congestive heart failure. The technique of operative nephrectomy was mentioned in only nine of the 21 reports. In six the renal pedicle was ligated en masse. The remaining three had postoperative wound complications including hemorrhage and abscess formation.

In addition to the arteriovenous fistula, this patient had bacterial endarteritis, an unusual but well recognized sequel of arteriovenous fistulas.⁹ This is not surprising because bacterial endarteritis can form on any portion of the vascular tree where turbulence produces endothelial trauma.¹⁰ The clinical signs of endarteritis are similar to

Figure—Aortogram demonstrating left renal artery-renal vein fistula with rapid filling of inferior vena cava.

*Chief Resident, Division of Urology, University of Minnesota Hospitals, Minneapolis, Minnesota.

†Available upon request.

endocarditis except that peripheral embolic phenomena, such as splinter hemorrhages, are absent. The infecting organism is usually streptococcus viridians although in the present case staphylococcus, coagulase positive, was found. In most cases the infection can be controlled or eliminated with intensive antibiotic therapy after which the fistula should be excised.

Summary

The literature suggests that post nephrectomy arteriovenous fistulas result from either mass ligation of the renal pedicle or from postoperative

wound complications such as hemorrhage or abscess. A bruit over the involved flank is characteristic and signs of high cardiac output including congestive heart failure may be present. These patients may also have bacterial endarteritis at the site of the A-V fistula. Their treatment consists of intensive antibiotic therapy followed by excision of the arteriovenous fistula. This is the first documented report in the English literature of a post nephrectomy arteriovenous fistula which occurred without associated mass ligation of the renal pedicle or postoperative wound complications.

Cover Photo "Country Doctor"

Dr. John Bartness, a radiologist now practicing in Phoenix, Arizona, told the editors he had always admired the old time country doctor. "He seemed to be an institution all in himself and required a great deal of stamina." This admiration of the family doctor started when he was a child and was the reason that he painted the "Country Doctor." Dr. Bartness has been painting since 1961, has never had a lesson and is self taught.

The old time buggy was purchased from a farmer who lived near Minnesota Lake for fifty dollars. The horse was given to him by a patient who had carcinoma of the breast who told him never to sell or give the horse away. Unfortunately the horse had the heaves (emphysema) quite badly and had to be put away. He had a lot of dedication and heart and would take the doctor to the hospital in Albert Lea whenever he was called.

While practicing medicine in Albert Lea, Dr. Bartness's biggest hobby was Judo and he received a black belt in Judo after a number of years. He taught Judo in Albert Lea for 14 years, trained over 2000 students in Albert Lea and vicinity. In March of 1972, his girls Judo team performed at the State High School Basketball Tournament at Williams Arena.

In art he was a member of the Albert Lea Art Center and one of the founders of the Annual Outdoor Art Festival.

In medicine he was chief of radiology at Naeve Hospital in Albert Lea for 17 years and founded the Naeve Hospital School of X-Ray Technology in 1956.

Chronic Granulocytic Leukemia in Children

HERBERT A. COOPER, M.D.* and MURRAY N. SILVERSTEIN, M.D.*

CHRONIC MYELOPROLIFERATIVE diseases rarely occur in childhood.¹ A 20-year retrospective review at our institution revealed that nine children had chronic granulocytic leukemia and one child had polycythemia rubra vera. We found no child with agnogenic myeloid metaplasia or hemorrhagic thrombocythemia. The purpose of this communication is to review our experience with chronic granulocytic leukemia in childhood in relation to its clinical course, hematologic findings, and response to therapy.

Our Series

The records of all patients 12 years old or younger who had myeloproliferative syndrome or chronic granulocytic leukemia were reviewed. The study, covering the period from 1950 to 1970, revealed that nine children had chronic granulocytic leukemia. A diagnosis of chronic granulocytic leukemia was acceptable if the following criteria were met: (1) splenomegaly, (2) total leukocyte count of 100,000/cu mm or greater associated with myeloid immaturity, (3) a bone-

marrow aspirate that revealed striking granulocytic hyperplasia with a bulge of cells at the myelocyte level, (4) the presence of the Philadelphia (Ph') chromosome, if the study was done, and (5) the absence of any condition known to produce a continuing granulocytic leukemoid reaction, for example, infections or stress.

Findings

Table 1 gives, for each patient, the age, sex, initial hemoglobin level, leukocyte and differential counts, platelet count, presenting symptoms, and physical findings at the time of diagnosis. Only two patients (Cases 6 and 8) had chromosome analysis, and the Ph' chromosome was positive in both. In all patients, marrow aspirations and sections were compatible with a diagnosis of chronic granulocytic leukemia.

Table 2 describes the duration of life from diagnosis till death and the modes of therapy employed.

Comment

Various studies have reported that chronic

granulocytic leukemia accounts for approximately 2.5% of all forms of leukemia in childhood.²⁻⁵ At our institution, approximately 400 patients with other forms of childhood leukemia were seen during the 20-year period study, making an incidence of chronic granulocytic leukemia about 2.5% of all childhood leukemias. Cooke⁴ suggested that the clinical course of chronic granulocytic leukemia in childhood might take two forms: juvenile and adult. This concept was reinforced more recently by Reisman and Trujillo⁶ and Hardisty et al.⁷ Data from our series further supports this conclusion: three of our patients (Cases 1, 2 and 3) had features of the juvenile disease and six (Cases 4, 5, 6, 7, 8 and 9) had the adult form. We emphasize that the juvenile disease occurs much more frequently in the very young child and that the adult form of the disease tends to occur at a later age (five years old or older). In addition to earlier age at onset, patients with juvenile chronic granulocytic leukemia tend to have lower leukocyte counts (less than 200,000/cu mm), lower platelet counts (less than 150,000/cu mm), in agreement with the findings of others.^{6,7} Children in our series with juvenile chronic granulocytic leukemia had a more virulent clinical course, poorer response to therapy, and a shortened survival time. Neither the sex of the patient nor the degree of anemia when the disease is diagnosed seems to aid in differentiating the juvenile form from the adult form.

Hardisty et al.⁷ reported four patients with the juvenile form and four patients with the adult type and suggested that splenic enlargement was greater in the adult type and lymph node enlargement and rash were more prominent in the juvenile form. In our series, neither the degree of lymph node enlargement nor the presence of splenomegaly was helpful in differentiating the two types. Rash

was not seen in any of our patients with the juvenile form.

Hardisty et al.⁷ noted a higher proportion of blasts, monocytes, and lymphocytes in their patients with the juvenile form. Our series does not reflect this. Bernard and associates⁸ have classified the juvenile form as seen in children as myelomonocytic leukemia. Data on three juvenile patients in our series do not support such a hematologic diagnosis on the basis of morphologic findings.

Reisman and Trujillo⁶ and Hardisty et al.⁷ have suggested that the juvenile and adult forms in childhood may be further differentiated on the basis of the Ph' chromosome. Interestingly, one of our patients (Case 6), who had a Ph' chromosome, survived only 10 months after diagnosis despite having clinical features and hematologic features suggesting the adult form of the disease.

Another finding suggested as helpful in differentiating the juvenile form from the adult form in children has been the presence of increased levels of hemoglobin F in the juvenile form. Initially noted by Beaven et al.³ in two children, Hardisty et al.⁷ also noticed increased hemoglobin F levels in patients with the juvenile type. The latter authors further observed normal hemoglobin F levels in three patients with the adult type. Bloom et al.⁹ reported an eight-month-old infant with the adult type who had the Ph' chromosome. This patient also had persistently normal levels of hemoglobin F. Unfortunately, none of our patients had hemoglobin F levels measured.

Hardisty et al.⁷ summarized the survival of 29 patients with the juvenile type and 58 patients with the adult type. Mean survivals were nine months for the former and 33 months for the latter. Treatment of these 87 patients varied. Interestingly, all nine patients in our series primarily received radiation therapy. In our series, the

mean survival of the three patients with juvenile form was 8.3 months as compared to that of 30 months for the six patients with the adult type. These data suggest that radiation therapy may not be the modality of choice for either form of the disease. Perhaps a more aggressive combined chemotherapeutic approach with immunotherapy is best in the juvenile form and a combined chemotherapeutic approach is warranted in the adult type. In our series, conceivably, the patients with the Ph' chromosome who had other features of the adult form did not live as long because radiation therapy was used.

Our experience with this disease agrees with the observations of others that two forms exist. The juvenile form seems to be characterized by a younger age at onset, lower total leukocyte count, lower total platelet count, and shortened survival. The adult form in children seems to occur after the age of five years and appears to be associated with a higher total leukocyte count in the absence of thrombopenia. The presence of the Ph' chromosome may well portend longer survival. Further exploration of the levels of hemoglobin F is necessary to determine if a relationship of this parameter to the adult form exists exclusively.

To explain the existence of two forms of childhood chronic granulocytic leukemia, Hardisty et al.⁷ have proposed that the juvenile form may be a congenital disease and that the presence of

increased levels of hemoglobin F may reflect a prolongation of fetal erythropoiesis. However, except for the younger age of onset of this form in children, no direct evidence supports this concept. In comparing our data with the observations of others, the single most important determinate as to the form that the disease will take in childhood depends on the age at onset when the diagnosis is made. One cannot help but speculate that the state of maturity of the bone marrow and the internal hormonal milieu at the time of the leukemic insult are of prime importance in determining the clinical course.

Summary

In a 20-year period at the Mayo Clinic, nine children with chronic granulocytic leukemia were seen. Three patients had the juvenile form, which is characterized, at diagnosis, by lower total leukocyte and platelet counts, a younger age, a shortened survival (mean 8.3 mo.), and a poor response to therapy. Six patients had the adult form, which is characterized by a later age at onset, higher total leukocyte and platelet counts, longer survival (mean 30 mo.), and a better response to therapy. Two patients had positive Philadelphia chromosome preparations. Data suggest that the age of the patient at diagnosis is important in determining the disease course.

aluminum and magnesium hydroxides with simethicone

STUART PHARMACEUTICALS | Division of ICI America Inc. | Wilmington, Del. 19899 | Pasadena, Calif. 91109

He has Trichomonas vaginalis?

It's his infection but her problem...

Men with trichomonal infection are virtually always asymptomatic, which is why they seldom know they have the disease. But many do have it, nevertheless.

Trichomonal infection is so common that estimates¹ indicate one out of every four women of reproductive age has the disease. *Almost half of the husbands of women infected with Trichomonas vaginalis have it, too.*^{2,9}

CONCURRENT THERAPY WITH FLAGYL PROVIDES ALMOST CERTAIN CURE FOR BOTH OF THEM.

- It is the most effective drug available for the treatment of trichomoniasis in both men and women.
- In men, it eliminates infection from the genitourinary tract.
- In women, it eliminates trichomonal infection from the vagina, the paravaginal crypts, cavities, and glands.
- Consistent cure rates above 90 percent are to be expected. The rate often approaches 100 percent.
- Simple, sure treatment for women: One 250-mg. tablet three times daily for ten days.
- Simple, sure treatment for men: One 250-mg. tablet twice daily for ten days concurrent with treatment of the female partner.
- Side effects are generally mild and infrequent.
- Flagyl is economical because it is so effective.

Flagyl[®] can cure them both.

(metronidazole)

Indications: For the treatment of trichomoniasis in both male and female patients and in the sexual partners of patients with a recurrence of the infection provided trichomonads have been demonstrated by wet smear or culture. The oral tablets are indicated also for acute intestinal amebiasis (amebic dysentery) and amebic liver abscess.

Contraindications: Evidence or history of blood dyscrasia, active organic disease of the CNS, the first trimester of pregnancy and a history of hypersensitivity to metronidazole.

Warnings: Use with discretion during the second and third trimesters of pregnancy and restrict to those pregnant patients not cured by topical measures. Flagyl (metronidazole) is secreted in the breast milk of nursing mothers. It is not known whether this can be injurious to the newborn.

Precautions: Mild leukopenia has been reported during Flagyl use; total and differen-

tial leukocyte counts are recommended before and after treatment with the drug, especially if a second course is necessary. Avoid alcoholic beverages during Flagyl therapy because abdominal cramps, vomiting and flushing may occur. Discontinue Flagyl promptly if abnormal neurologic signs occur. Exacerbation of moniliasis may occur. In amebic liver abscess, aspirate pus during metronidazole therapy.

Adverse Reactions: Nausea, headache, anorexia, vomiting, diarrhea, epigastric distress, abdominal cramping, constipation, a metallic, sharp and unpleasant taste, furry or sore tongue, glossitis and stomatitis possibly associated with a sudden overgrowth of *Monilia*, exacerbation of vaginal moniliasis, an occasional reversible moderate leukopenia, dizziness, vertigo, incoordination and ataxia, numbness or paresthesia of an extremity, fleeting joint pains, confusion, irritability, depression, insomnia, mild erythematous eruptions, "weakness," urticaria, flushing, dryness of the

mouth, vagina or vulva, pruritus, cystitis, a sense of pelvic pressure, dyspareunia, fever, polyuria, incontinence, decreased libido, nasal congestion, proctitis, pyuria, darkened urine have occurred in patients receiving the drug. Patients receiving Flagyl may experience abdominal distress, vomiting or headache if alcoholic beverages are consumed. The taste of alcoholic beverages may also be modified. Flattening of the T wave may be seen in ECG tracings.

Dosage and Administration: For trichomoniasis. *In the female:* One 250-mg. tablet orally three times daily for ten days. The course may be repeated if required in especially stubborn cases; in such patients an interval of six weeks between courses and total differential leukocyte counts before, during and after treatment are recommended. Vaginal inserts of 500 mg. are available for use, especially in stubborn cases. *When the vaginal inserts are used,* one 500-mg. insert is placed

vaginal vault each day for ten days and dosage is reduced to two 250-mg. tablets during the ten-day course of treatment. Do not use the vaginal inserts as the sole therapy. *In the male:* Prescribe Flagyl when trichomonads are demonstrated in the genital tract, one 250-mg. tablet two times daily for ten days. Flagyl should be taken by partners over the same ten-day period as prescribed for the male in conjunction with the treatment of his female partner.

Amebiasis. *Adults:* For acute intestinal amebiasis, 750 mg. orally three times daily for 10 days. For amebic liver abscess, 500 mg. orally three times daily for 5 to 10 days. *Children:* 35 to 50 mg./kg. of body weight in 24 hours, divided into three doses, for ten days.

Forms: Oral tablets 250 mg.
Vaginal inserts 500 mg.

Rural General Practitioners

RURAL GENERAL practitioners (RGP) are recruited from medical students and young doctors with exposure to rural living. And the greater the exposure, the greater the likelihood of the medical graduate adopting the life of the RGP. This is the conclusion that is drawn from the comparative study of the RGPs vs. UGPs (urban general practitioners).

Carter et al.* found there is less chance of success in a small town setting of the city-bred, urban trained physician transplanted to the market town. The best country doctor material is the country boy temporarily transplanted to the city for his education, but whose roots are not in the city but in the country surroundings of his formative years.

The usual criteria for entrance to medical school used by admissions committees are: (1)

Grade-point averages and (2) medical aptitude as determined by the medical aptitude test. The effect of adding additional criteria—race, sex, place of birth, the size of the town the applicant grew up in, any other criterion whatsoever—necessarily must vitiate the criteria of scholastic excellence and medical aptitude.

But people will continue to demand primary medical service to be given in their area, and no amount of consultative service available elsewhere will compensate for absence of primary care at the source.

The need for doctors in the rural areas in Minnesota must be met.

Dr. Carter, who is the Dean of the Duluth Medical School, suggests one way to get more RGPs—select more rural people for medical training.

Medical Writing and Cover Photograph Awards: 1972

EACH YEAR THE Board of Editors selects the best original article and the best cover for the year before.

The winners for 1972 are:

Best Cover: "November Song," photograph by John P. Wendland, M.D., Minneapolis ophthalmologist.

Best Article: "Idiopathic Scoliosis—Current Concepts in the Treatment," by Robert B. Winter, M.D. and John H. Moe, M.D.

Analyzing the Board

Each year I try to analyze why the Board selected the winners it did. Psychoanalyzing one person is hard enough. Psychoanalyzing a Board of Editors, each of whom has his own piece of mind, is a job of a completely different magnitude. It would be tough for a psychiatrist to analyze such a group of spirits. Nevertheless I shall have a go at second guessing the Board.

November Song

First, "November Song." Frankly, I think the Board picked this cover because the photograph displays the proper perspective, focus, clarity and composition. Besides, it's a good picture. Not only that, it's a good picture of a field of Minnesota corn shocks taken on a beautiful autumn day.

For your information, there may have been a sympathy vote among the Board. You see, when the picture appeared, the Editors and the photographer who described it made a shocking mistake. Quoting Doctor Wendland, the Editors wrote: "He recalls the area as being around Red Wing and at the time was impressed with this particular field of wheat as this method of harvesting wheat has been disappearing from the farm scene." The wheat stacks, as many readers promptly informed us, were really corn shocks. Anyway, we apologize. Next time we'll try to have a better sense of humor.

Idiopathic Scoliosis

Now, the article . . . Here the Board was nearly

unanimous. And for good reasons. Doctor Winter and Moe, who are Medical Director and Chief of Staff at Gillette Children's Hospital, St. Paul, know their subject matter and write about it well. You can tell that from the clarity and tone of the prose.

For example, here's the opening paragraph:

"Scoliosis, once considered the scourge of orthopedics, has entered a new phase. In the past treatment of this condition was so poor that one could only stand by and watch the curve get worse. Finally, when it got bad enough, a difficult fusion operation was done as a last resort. Such pessimism no longer has a place in the treatment of this condition, and the entire concepts of treatment have changed within the past ten years."

And a paragraph on treatment:

"There are three ways to treat these curvature. The *first* is to do nothing except to observe the child periodically, including the taking of X-rays to see whether a curve is present, or if present whether it is progressive. This type of 'observational treatment' is rarely justifiable. *As noted previously, physical therapy and exercises do not have not, and never will correct an already present curvature of the spine.* Exercises are important when properly combined with a Milwaukee Brace or fusion program."

And a comment on the Milwaukee brace:

"Therefore, when applied *early enough*, worn *long enough*, and removed *slowly enough*, the curvature will be completely halted in its progression and never reach a significant degree of curvature."

This is obviously authoritative stuff. The proverbs ring true, and the authors buttressed their words with excellent X-rays and photographs.

Again the Board has made excellent choice for the best cover and article.

Richard L. Reece, M.D.
Minneapolis, Minnesota

Fibercolonoscopy

IN THIS ARTICLE Latts, Borken, and Kaplan* have shown the value of Fiberoptic Colonoscope as a diagnostic tool, although the scope used was only 80 cm in length. The development and progress of this instrument have been rapid. Now, the longer scopes of 100 cm and 185 cm, with the deflection to four directions, are available, which can be passed to the left transverse colon and cecum, respectively. The most recent progress of this instrument is its therapeutic application. Wolff and Shinya¹ have proved that polypectomy via Fiberoptic Colonoscope, when

properly done, is a safe procedure. The procedure is a potential hazard. Possibility of bleeding and perforation should always be kept in mind. It is the endoscopist's judgment to carefully select the cases. Up to the present time polypectomy through the scope should be performed only in pedunculated polyps or in the small, benign-looking sessile polyps. A certain skill must be acquired to use the instrument efficiently and safely.

Santbat Nivatvongs, M.D.
University of Minnesota

Do You Drink A Quart of Whiskey A Day?

WEINBERG'S ARTICLE "Why Do Alcoholics Deny the Problem?"* illustrates the type of patient whose alcoholic history is likely to be totally suppressed and undiscovered by the physician.

I have found the question "Do You Drink A Quart of Whiskey A Day?" helpful in screening the alcoholic patient. The answer is invariably "no." The non-alcoholic, however, reacts by some indication that the query is ridiculous. He may laugh or appear shocked by the very question. The alcoholic turns it over in his mind and his negative answer gives the impression that he accepts the question as legitimate and ordinary to be answered with a flat "no."

The alcoholic as an evil man, an immoral per-

son, mentally inferior, possessed by the demon rum to be pitied or shunned by polite society, is a stereotype accepted by many including, unfortunately, physicians. If we are to make any progress in the treatment of alcoholism we must adopt a professional attitude toward the sick alcoholic confronting us.

Doctors are accustomed to suppressing emotions in themselves in their handling of disagreeable patients. Perhaps the failure to accomplish any significant improvement in the alcoholic patient stems in part from our own suppressed but never entirely hidden attitude of disgust for the habit rather than sympathy for the diseased individual.

Reuben Berman, M.D.
Editor

Winston Miller, M.D.

The Northlands Regional Medical Program should not be allowed to close its books without some recognition from the doctors of the state of the important contributions to post graduate medical training made by Dr. Winston R. Miller, its program director.

A special mention should certainly be made of the emphasis placed here on educational aids to practice instead of the establishment of the large centers of treatment contemplated at the outset by Washington planners. It is certain that much of the work done under Dr. Miller's direction will persist as a permanent aid to the practice of medicine in Minnesota.

DIRECTOR of MENTAL HEALTH

We are seeking a psychiatrist to direct the Milwaukee County Mental Health Center, a comprehensive community mental health center, organized into six catchment area programs including outreach stations located within the community. 1,000 acute and long-term psychiatric beds; an ultra modern day hospital; and, a soon to be completed 180 bed inpatient resident and day care treatment center for children and adolescents. The Center is a principal psychiatric teaching resource for the Medical College of Wisconsin and has training programs for interns, residents, nurses and other students.

Requires Wisconsin licensure or eligibility for same and at least 5 years comprehensive experience as a mental health director, educator, or administrator preferably in an accredited mental health program, university or hospital.

This is a timely opportunity since we can offer the person appointed to this position the chance to make several critical appointments to new subordinate positions. Excellent employee fringe benefit program and salary. Send vita to:

Budd-Chiari Syndrome

An Etiologic and Therapeutic Enigma

THE CAUSE OF THE Budd-Chiari syndrome is unknown in 70% of the cases. Polycythemia vera is associated in 30% of cases.¹ A small percentage of cases have other associated conditions, which have been enumerated in the discussion of the case report by Retzlaff and Mongé in the January issue* of MINNESOTA MEDICINE.² Although the authors of this current report assert that their patient had polycythemia rubra vera, data (that is, blood volume studies, status of megakaryocytes in bone marrow, platelet counts, leukocyte alkaline phosphatase, etc.) are lacking to confirm the diagnosis. A secondary cause for polycythemia is suggested inasmuch as the hemoglobin level decreased after rehydration and removal of the pelvic leiomyoma, a reported cause of erythrocytosis.³ Apparently, hypernephroma, oral contraceptives, membranous obstruction of the inferior vena cava, and other causes of hepatic vein occlusion can be excluded. This case probably should be one of the Budd-Chiari syndrome of unknown cause.

Although the overall prognosis in hepatic vein occlusion is poor, patients may survive for several years, and some have recovered completely after cessation of oral contraceptives when these agents have been implicated as an etiologic factor⁴ and after vigorous treatment of polycythemia vera.⁵ The treatment of Budd-Chiari syndrome is largely symptomatic. In the acute stages, patients are heparinized and their ascites treated by restriction of salt and fluid and by diuretics. If hepatic coma supervenes, it should be treated in the usual fashion (protein restriction, enemas, and neomycin). In late stages of the disease, side-to-side portal-caval anastomosis should be considered and has been successful,⁶ if the vena cava is patent. In caval obstruction, decompression has been attempted by a Y-shaped Dacron graft connecting the right atrium, superior mesenteric vein, and right internal iliac artery;⁷ a Teflon graft between the proximal end of the splenic vein and transected distal end of the left pulmonary artery to the left lower lobe;⁸ a Teflon graft between the proximal splenic vein and the right atrium;⁸ or transposition of the spleen into the left thoracic cavity.⁹ The infrequency of these operations and lack of controlled studies make it impossible to assess their

overall value.

Although the role of surgical procedures in the treatment of this syndrome remains controversial, if the site of obstruction is delineated and no underlying otherwise treatable conditions are present, definitive surgery may be successful. An investigation should be made of young to middle-aged persons with severe ascites who do not have any clinical or histologic features of cirrhosis so that correctable lesions might be identified. Hepatic venography in conjunction with pressure measurements is most important. Constrictive pericarditis and heart failure must be excluded by clinical testing, and, in doubtful cases, by right atrial pressure studies to eliminate these possible causes of hepatic congestion.

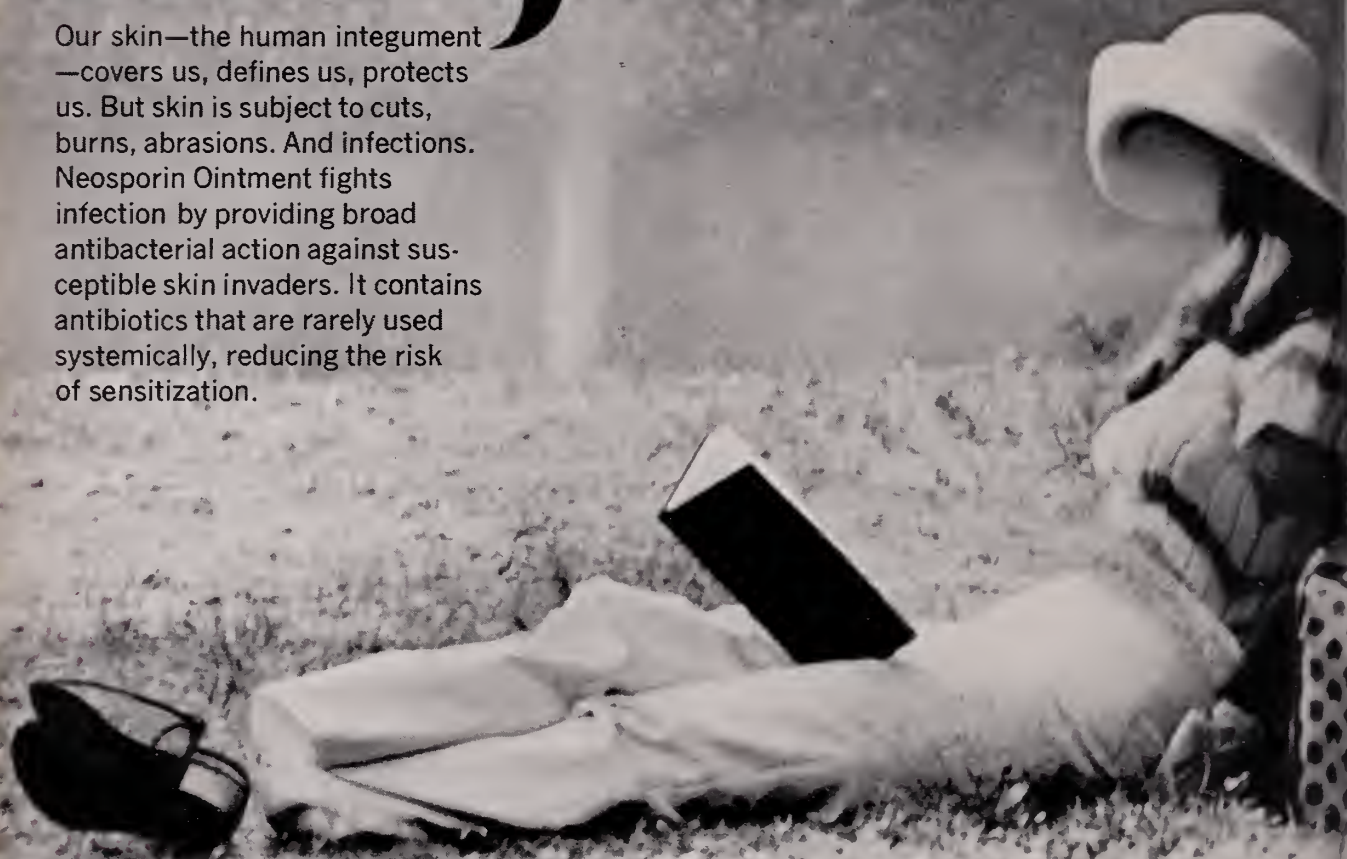

Recently, membranous or fibrous diaphragms occluding the inferior vena cava above the entrance of the right hepatic vein have been identified and treated by transcatheter membranotomy.^{5,10-13} Surgical procedures also have been attempted to relieve inferior vena caval obstruction; these include anastomosis of the azygous vein to the medial side of the inferior vena cava below the obstruction¹² and Dacron grafts between the inferior vena cava and the right atrium.^{12,14} More recently, decompression of the hepatic vein and inferior vena cava under direct vision by means of total circulatory arrest, profound hypothermia, and a pump oxygenator has been successful.¹⁵ Unfortunately, many patients will not be relieved of venous obstruction by surgical treatment because the thrombosis is usually extensive. Even if inferior vena caval obstruction is relieved, patients with remaining occlusion of all hepatic veins have a poor prognosis.¹³ Patients who undergo exploratory operations without a definitive procedure have a high mortality rate.⁵ Exploration rarely contributes information that cannot be obtained otherwise. Surgery in the acute stages of this syndrome should be avoided unless an operable lesion can be anticipated.

Progress has been made in uncovering some causes of Budd-Chiari syndrome and new therapeutic surgical procedures have been attempted. Currently, the vast majority of patients with this infrequent syndrome will die of their disease. With further study the pathophysiology of this process

*Retzlaff K and Mongé JJ: Polycythemia vera with acute Budd-Chiari syndrome. *Minnesota Med* 56:1:60, 1973.

Integument!

Our skin—the human integument—covers us, defines us, protects us. But skin is subject to cuts, burns, abrasions. And infections. Neosporin Ointment fights infection by providing broad antibacterial action against susceptible skin invaders. It contains antibiotics that are rarely used systemically, reducing the risk of sensitization.

INDICATIONS: *Therapeutically*, used as an adjunct to appropriate systemic therapy for topical infections, primary or secondary, due to susceptible organisms, as in: • infected burns, skin grafts, surgical incisions, otitis externa

- primary pyodermas (impetigo, ecthyma, sycosis vulgaris, paronychia)
- secondarily infected dermatoses (eczema, herpes, and seborrheic dermatitis)
- traumatic lesions, inflamed or suppurating as a result of bacterial infection.

Prophylactically, the ointment may be used to prevent bacterial contamination in burns, skin grafts, incisions, and other clean lesions. For abrasions, minor cuts and wounds accidentally incurred, its use may prevent the development of infection and permit wound healing.

CONTRAINDICATIONS: Not for use in the external ear canal if the eardrum is perforated. This product is contraindicated in those individuals who have shown hypersensitivity to any of the components.

PRECAUTION: As with other antibiotic preparations, prolonged use may result in overgrowth of nonsusceptible organisms and/or fungi. Appropriate measures should be taken if this occurs. Articles in the current medical literature indicate an increase in the prevalence of persons allergic to neomycin. The possibility of such a reaction should be borne in mind.

Complete literature available on request from Professional Services Dept. PML.

Renal Failure Caused by Cholesterol Emboli

BLOOM, WINTHROP AND SAROSI* describe in the December issue of MINNESOTA MEDICINE a clinical disorder that has received inadequate attention in the medical literature—renal failure due to atheromatous emboli. The individual at greatest risk is the male over age 60 who has advanced ulcerating atheromatous disease of the aorta. Frequently hypertension, nephrosclerosis, and diabetes mellitus are associated. An aneurysm may or may not be present.

The diagnosis is made most readily when it occurs during surgical repair of an abdominal aortic aneurysm. Manipulation of the atherosclerotic vessel releases variable amounts of eroded atheromatous debris into the renal arterial tree. The main renal arteries or their primary branches are occluded by large atheroemboli. Smaller cholesterol emboli occlude the arcuate and interlobular vessels. The resulting loss of renal function usually is permanent. Theoretically renal blood flow may be increased by removing atheromatous material from the largest vessels, but simultaneous involvement of the smaller branches prevents significant improvement. Cholesterol emboli also may be released during rupture of an aneurysm prior to surgical intervention.

Whether oliguric or non-oliguric, sudden renal failure due to atheromatous embolism following aneurysmectomy is to be differentiated from the more familiar "acute tubular necrosis" resulting from ischemia. With good preoperative hydration, maintenance of adequate arterial oxygenation during anesthesia, and use of osmotic or saluretic diuretics to maintain adequate urine volume, acute tubular necrosis secondary to the repair of aortic aneurysms occurs less frequently now than was the case just a few years ago. However, renal failure due to atheromatous embolism assumes increasing significance. Differentiation between the two syndromes can be made by renal arteriography. Occlusion of even the smaller arcuate or interlobular arteries can be detected by X-ray.

A diagnosis frequently missed is cholesterol embolism occurring spontaneously as illustrated by the case reports of Bloom, et al. Showers of cholesterol crystals from various parts of the aorta may be released over a period of time, producing multiple small infarcts in many organs. Renal involvement is only one part of the total picture. Recurrent abdominal pain results from occlusion of branches of the mesenteric or pancreatic arteries. Livedo reticularis, petechiae, painful nodules and purple toes indicate emboli to the extremities. "Small strokes" may occur if the

ascending aorta is involved. Loss of renal function frequently is accompanied by an accelerated hypertension. The small renal infarcts produce a "micro-Goldblatt phenomenon"¹ with activation of the renin-angiotensin-aldosterone system. Again the diagnosis can be established by renal arteriography, or by histopathologic examination of the kidney. The presence of cholesterol crystal clefts with a surrounding giant cell foreign body reaction is diagnostic. Treatment by anticoagulation is not beneficial, but may be detrimental as Bloom and

associates observe.

The individual who loses renal function during the repair of an aortic aneurysm may be a suitable candidate for chronic hemodialysis, assuming good cardiac and cerebral function. Today many patients in their seventh and eighth decades of life are maintained quite well by long-term dialysis. Little can be done for the individual with multiple organ involvement.

Indians, Alcohol and Violent Death

THERE IS FAR more myth than factual foundation in our understanding of the American Indian. This must be as true of their health problems as it is for any other aspects of their lives. Westermeyer and Brantner* are to be commended for bringing to our attention some of the special social and health problems of the Chippewa Indians of Minnesota.

In this article they display the startling fact that one-fourth of all Indian deaths are due to accident or violence. Such incidents are, in the case of Indians, the ranking cause of death. Further, it is assumed that one of the major health problems of the Indians is their excessive use of alcohol. This is not so easily proved because the criteria for excessive use of alcohol vary within any culture and certainly across subcultures. The third striking feature with respect to their health in contrast to Caucasians, is their life span. It is substantially shorter than for whites and they are far less plagued with degenerative diseases. It may be, but it is not clearly shown in this paper, that this is due to premature demise because of accidental and violent death. The authors sought to determine, however, if such a relationship did exist.

Indicators such as a sampling of blood alcohol may be somewhat skewed by factors of race and

age, especially in association with violent death, because such samplings were more frequently drawn in young Indians dying under those circumstances. The method used by the authors on correcting for age may not be as refined as they would have liked to relate accidents as the cause of death in the overall population. Although such cross-cultural studies such as this are of interest, they cannot add substantially to the difficult problem of showing conclusively causative relationships. For example, if we were to examine the relationship between alcoholism and accidents as a cause of death in whites in the general population, I doubt if we would strike a comparison with the Indians or the blacks. By the same token, if we wish to examine the possibility of a relationship between Indian life style, alcoholism, or accidents and violence as it relates to early age death in Indians, such relationships could be examined without racial comparisons. As the authors have indicated, it might be more meaningful to look at life styles within Indian subgroups.

In any event, cross-cultural studies do call to our attention that certain of our minority citizens have many special health problems which have not come to our attention because they have been lost in the statistics for the general population.

OLD DOC HESS SAYS: Some people seem to proclaim that they know more about your business than you do. . . . C.O.R.

Letters to the Editor

To The Editor:

Dr. Fehr's editorial in the May issue of MINNESOTA MEDICINE¹ entitled "Infectious Complications Following Abortions" implies (1) that the advocates of free-standing abortion clinics are minimizing the complication rate because of the poor follow-up on their patients.² (2) He also deplores the "no-touch" technique and the absence of a sterile (and expensive) hospital setting in the performance of pregnancy termination.

His arguments are apparently based on the recent admission to Minneapolis General Hospital of several patients with post-abortion pelvic infection.³ These patients received primary care at several out-of-state clinics. We have no idea how many total patients are represented by these infected few appearing at Minneapolis General Hospital. In view of the fact that 1000 women a month were being forced at that time to leave Minnesota and travel across the country and back to obtain medical care, it is not at all surprising that some of these inevitable complications would eventually end up at Minneapolis General Hospital. It is unfortunate that these patients were not given primary care at home thereby possibly avoiding such complications, but we can draw no conclusions from the article of Gaziano and Kaplan³ as to the actual incidence of infection following legal abortion.

If Dr. Fehr would peruse the current literature he could find a number of answers to the questions raised by his editorial regarding such incidence (See references 4-15, inclusive).

May I quote from a recent survey of the subject: "Retained products of conception frequently require repetition of the surgical evacuation for the control of either bleeding or associated infection. The incidence of this requirement varies between 2.9 to 3.5 per 1000 patients."¹⁰

Dr. Tietze in the JPSA study⁶ revealed that the rate of postoperative infection and hemorrhage is actually lower in the freestanding clinics than in the hospitals, and also lower in the outpatient hospital group than with the in-patient hospital group. These figures are based on those patients with whom follow-up contacts were made. In defense of the follow-up procedure of our ambulatory clinic, we are able to trace up to 70% of our patients by means of telephone calls, patient's follow-up forms, physicians' follow-up cards, and contacts with referring agencies.

Dr. Fehr empirically claims that the costly sterile technique of a surgical operating room is necessary to protect "the life and health of those women who choose to be aborted."¹ But the JPSA report⁶ found that it was safer for a woman to have a vacuum aspiration procedure in a free-standing clinic than in a hospital. As far as mortalities are concerned, we have had none in over 28,000 procedures (Preterm Clinic, Washington, D.C.). Nathanson reports no mortalities in over 30,000 procedures.^{7,8}

"The minimal sterile technique used in a free-standing ambulatory abortion clinic," so deplored by Dr. Fehr, is establishing excellent records throughout the world.^{12,13} It is true that prior to the uniform legalization of abortion accurate statistics on abortion patients were extremely difficult to obtain. But, New York State with its almost three-year experience has done a magnificent job in record keeping and in documenting the safety of the various techniques and facilities for the rest of the country. Let us give their statistics the attention that they deserve.⁴

In view of the wide-spread effort to reduce the cost of medical care, it was

surprising to note Dr. Fehr's implication that all abortion patients be hospitalized. With pre-admission screening and hospital review committees many procedures will soon be assigned for outpatient treatment, regardless of insurance coverage, and this is the only way that the high costs of medical service will be curtailed. Free-standing abortion clinics are pioneering the way for the delivery of many surgical and medical services on an out-patient basis.

In 1973, the free-standing clinic serves as the main source of delivery of this highly specialized service. At the present time, the free-standing clinic can terminate first trimester pregnancies far more economically and expeditiously and with a better safety record than the usual hospital.

I am well aware of the surge of activity around the country among the members of our profession in an attempt to implement the new abortion laws. It is vitally important that these facts be presented in a straight-forward manner.

To The Editor:

The letter of Dr. Hodgson repeats statistics on the safety of ambulatory abortion which we have all heard many times before. The article of Kaplan and Gaziano* gives us facts which definitely cast a shadow of doubt on the validity of those statistics. Unfortunately, the statistics quoted in Dr. Hodgson's letter are those by proponents of ambulatory abortion and not the statistical analyst. An old professor of statistics once warned us that one can prove anything he wished with statistics.

The article of Kaplan and Gaziano can not be refuted; therefore, we must view with caution the statistics of safety ensued by the proponents of ambulatory abortion.

Medical Morality and Medical Excellence

SEYMOUR HANDLER, M.D.*

IN TRADITIONAL RELIGIONS, morality involves questions of right and wrong. The less formal religions consider morality as the effect of our actions and thoughts on our fellow man. In this broader sense, and as it pertains to the practice of medicine, morality may be equated with medical excellence.

The patient depends on medical morality because the physician is the denominator of patient care. Who but the physician can the unsophisticated layman look to for guidance and protection in the complex and institutionalized maze that is medical care today. When every activity involving physician and patient serves to benefit the patient, pure medical morality exists. Unfortunately, in the past several decades, medical technology and activity have proliferated to a point where the practice of medicine is on a high level, but patient care lags behind. Somehow, in the whirlwind of activity in our offices and hospitals, we must control medical activism and be concerned solely with what is best for the patient.

How do we achieve a medical environment in which the welfare of the patient is given constant consideration. Many methods exist to improve medical care, and the succeeding suggestions are not exclusive.

A major factor in good medical care is frequent consultation. As the years roll by in a physician's practice, experience creates a sense of medical omnipotence, where diagnoses appear obvious, and where little is to be gained with another opinion. Unfortunately, what is considered "obvious" may turn out to be something else, and what is called experience is often repetition of error. True experience is an educational process in which we profit from mistakes or learn from our peers. A reasonable reliance on experience is acceptable in medical problems where the disease is self-limited or of little consequence. However, in the more serious illnesses seen in hospital situations, an additional opinion may offer new diagnostic insight and may avoid a traumatic or unnecessary procedure for the patient. An entirely new evaluation by a consultant, beginning from a zero information

base, without preconceived notions, often reveals a previously unconsidered diagnostic possibility. How difficult it is for we physicians to change direction in the evaluation of a patient problem; so easy to follow an already chosen path.

Consultation rates differ as widely as the talents of the physicians. Some good clinicians regularly seek consultation, while others infrequently seek help. Consultation need not be limited to the primary care physician. Specialists need help and patient care could not help but be benefited if specialists more frequently called in other specialists for additional opinions. In most instances, seeking consultation elevates the referring physician in the eyes of the patient, who then is firmly convinced that *his* doctor is truly concerned about his condition. Physicians who consider consultation an admission of inability or an unwarranted expense are mistaken, and the patient suffers for this error. Further, not only should consultation be more frequent, but the physician seeking help should choose the best consultant possible, the one most likely to be helpful to the patient. Too often, choice of consultant is based on convenience to the physician, habit pattern and personality factors. The consultant should be one who works well with the referring physician, because the art of medicine is involved in patient care. The physician should not fall into the habit of *always* calling the same consultant, when in a given case, more effective consultation is available.

A second place where patient care may be improved is avoidance of defensive medical procedures. Physicians who order extensive batteries of diagnostic procedures are often trying to substitute for diagnostic judgment. The diagnostic test most helpful to the patient is the test that confirms the clinician's impression. Obtaining a "complete workup" of diagnostic tests is not good medical care. Unless a diagnostic procedure entails little risk, small expense, and has at least some chance of providing information, such routine tests should be avoided. Of particular concern is extensive testing of senior citizens who are as well as could be expected for their age. The practice of perform-

*Minneapolis, Minnesota.

ing complex, tiring and expensive diagnostic tests on octogenarians without specific indication is not good service to elderly patients. Their longevity is proof that they have passed the test of years, and preventive medicine without symptoms in older patients is unwise. A similar line of reasoning pertains to procedures that are done out of concern for medicolegal litigation. Physicians should practice medicine, not law. In recent actions, "defensive medicine" has been successfully litigated against.

Another way to improve patient care is to guard against bandwagon psychology. New diagnostic and therapeutic procedures should be evaluated by competent investigators at appropriate centers, not studied on individual patients at community hospitals. The individual physician, in the complex interpersonal relationship developed with his patient, is in no position to evaluate a new procedure. Evaluation must divorce patient hope and physician optimism, and depend on "double blind" procedures in which as many variables as possible are eliminated. It is not necessary that a new surgical procedure be performed at every hospital, just because the hospital down the street is doing that operation. The procedure must justify itself,

with proof that patient care is improved.

Physicians must look upon the practice of medicine as a profession dedicated to the welfare of the patient, rather than as a convenient way to earn a good living and gain community prestige. Vital to this professional outlook is a willingness—nay, rather an intense desire—to make postgraduate education an integral part of every working day. We should not wait for our professional societies or the "government" to set minimal standards of continuing education or recertification. The informed physician is best able to evaluate the "advances" leaked to the news media by grant-seeking investigators. Real medical knowledge is available, not from the drug detail man, but in the medical literature and from regular attendance at hospital staff and specialty society meetings. "Keeping up" is hard work, requiring a regular expenditure of time, but gratifying, from the realization that the patient is better off. Continuing education may be the heart of medical excellence—knowing enough about one's field to best care for the patient.

Medical morality *is* excellence of medical care. By keeping the patient in mind at all times, and relegating the benefits to medical practice to the background, patients will be better served.

Request for Physician's Art Work

For many years the Board of Editors of MINNESOTA MEDICINE has recognized and supported photographic and other artistic talents of the members of the Minnesota State Medical Association publishing cover pictures in color of their work. Our series of color covers have received much favorable comment and many journals have followed us in the use of color art in this manner.

We solicit color photographs including pictures of all art forms created by members of the Association. These must be technically excellent to show off the subject to its best advantage.

Although in the past we have printed cover pictures depicting many distant parts of the world, photographs of life in Minnesota will be given preference. Pictures will be returned if identified with the name and address of the physician. Please submit your picture as prospective cover subjects to the Editor of MINNESOTA MEDICINE, 375 Jackson St., St. Paul, Minnesota 55101.

Endotracheal Intubation of the Newborn

MARTHA BURKE-STRICKLAND, M.D.*

ESTABLISHMENT AND maintenance of effective ventilation in the newborn often requires endotracheal intubation. Attending personnel should be able to carry out the procedure without delay when needed if neurological potential of the infant is to be preserved.

Indications

Resuscitation of the depressed baby at delivery.

Resuscitation of an infant with cardio-respiratory arrest.

Establishment of a clear airway in aspiration syndrome.

Assistance of respiration for the tiring premature.

Assistance of the infant with respiratory distress whose inability to maintain an adequate blood pH and blood gases cannot be corrected with mask assistance.

Complications

Complications which may be attributed to the procedure itself include laryngeal bruising and edema, laceration of vocal cords, pneumomediastinum, pneumothorax, intubation of the esophagus instead of the trachea, injury to the spinal cord.

Possible complications that may occur secondary to conditions of use of the endotracheal (ET) tube include ulceration, hemorrhage, necrosis scarring stenosis, obstruction, atelectasis and infection.

Precautions During the Procedure:

1. Protect the infant from chill stress.
2. Keep the head supported. Do not allow it to drop over the edge or the rim of the work surface.
3. Work quickly but calmly.

The Endotracheal Tube

A 3 mm uniform internal diameter, soft, flexible, nontoxic, bevel-tip plastic tube may be used to intubate most newborns. A 2.5 mm tube may be needed for infants weighing less than 1,000 grams. To facilitate passage of as large a suction catheter as possible, the male connector of the

standard 15 mm adapter should have an internal diameter as large as the internal diameter of the plastic ET tube. Length of the tube should be equal to one-fifth the crown-heel length of the infant. Adjustments in length should not be made by cutting the beveled end. The residual sharp edge increases the risk of trauma to the larynx and trachea. Warming the tube and adapter in hot water facilitates ET tube removal from and reapplication to the adapter.

The orange Cole type tube with a narrowed diameter at the tracheal end is not used in our unit. The flange shape prevents the ET tube from advancing too far into the trachea, however, this advantage of the Cole tube is outweighed by the increased pressure necrosis the flange may cause in the vocal cords; the greater difficulty in passing an adequate suctioning catheter; and increased dead space for the spontaneously breathing infant.

Other Equipment

There are many styles of laryngoscope blades from which to choose. The Forreger-Miller 0 for small prematures (less than 2,000 grams) and the Forreger-Miller one blade for the larger premature and full term infant used with a medium hook-on handle (C size batteries) have proven satisfactory. Keep the blade in the "off" position until ready to begin the actual tube placement.

Sterilized white pipe cleaners may be used as stylets for the endotracheal tubes if care is exercised to prevent injury by the wire end. Position the pipe cleaner in the tube so that one end extends almost to the bevel but does not protrude into the bevel opening. Bend the excess length of pipe cleaner over the adapter edge to form a hook that will prevent the pipe cleaner from sliding further into the tube. Shape the tube into a slight curve so that the bevel is in the same plane as the arc of the curve (Figure 1).

No. 8F and 5F suction catheters with thumb control and a source of vacuum controlled to deliver a negative pressure of 18-20 cm water, a hand resuscitator connected to a source of humidified oxygen, a Devilbliss 170 atomizer filled with 4% Lidocaine and an adjustable stool with castors complete the set up.

*Director of Newborn Services, Hennepin County General Hospital, Minneapolis, Minnesota.

Figure 3. Elastoplast

Figure 4. Suture in Wall of Endotracheal Tube Should not Obstruct Lumen

Suture in endotracheal tube ready to be sutured into elastoplast at points "X".

Tape in place with one half of strip wound around ET tube. (Expanded to show detail.)

Completed fixation of endotracheal tube.

Figure 5. Suturing and Taping Endotracheal Tube

Technique of Procedure

Position the baby on back with head slightly extended over a shoulder roll (Figure 2).

Clear secretions from the mouth and throat. Empty the stomach.

Holding the laryngoscope in the left hand, snap the blade into the "on" position, slide the blade into the left* side of the mouth angling from the corner to the midline at the base of the tongue. The slight curve at the end of the blade should slide into the valley between the epiglottis and the base of the tongue. When the epiglottis is visualized, lift the end of the laryngoscope blade to bring the larynx into view. Avoid using the upper lip and maxillary ridge of the infant as the fulcrum for this maneuver. It takes skill and strength to lift the blade by using the operator's hand as the fulcrum (Figure 2).

In the small premature infant, better visibility of the cords is maintained by keeping the blade in the side-to-midline position. Grasp the endotracheal tube adapter between the thumb and forefinger of the right hand. Introduce the ET tube from the right* corner of the mouth to the larynx in the posterior midline. Use a curving, pronating twist of the wrist to make the tip of the endotracheal tube follow the natural curve of the oral cavity. This should put the tube alongside the blade, but *not* in it, with the bevel tip right at the vocal cords. If the tone is poor, the cords will be gaping and the ET tube will slide into the trachea with no difficulty. If the cords are closed, wait for the next inspiratory effort to insert the bevel into the slit between the cords. Maintain the curving motion of the tube. Shoving the tube at the larynx will usually result in a misshapen piece of spaghetti over which the operator loses all control. If this happens, withdraw, reshape the tube in a curve and start over. Remove the stylet as soon as the tube enters the trachea. Hold the adapter securely in conjunction with the chin to prevent extubation and ventilate with the hand resuscitator. Check position by observing the rise of the chest and by listening over the stomach and over both sides of the chest during ventilation assistance. Breath sounds should be equal in both apices. If air rushes are heard over the stomach area then the tube is in the esophagus and not the trachea.

*Positions related to the operator's left and right as he faces the top of the infant's head.

Final position of the tip of the ET tube should be midway between the larynx and the carina. Confirm position with Xray and reposition immediately if necessary. A tube lodged in the right main stem bronchus compromises total ventilation and causes atelectasis in the nonventilated portions. It may lead to devitalization and infection if allowed to persist for several hours.

In the larger newborn, better control of the tongue will be obtained by bringing the handle end of the blade toward the midline position after the larynx is brought into view at the distal end of the blade. Overshooting the midline to the left narrows or obliterates the field of action. The maneuver for introducing the ET tube is the same for smaller infants.

When spasm of the cords prevents entry of the tube into the trachea, one quick topical spray with 4% Lidocaine to relieve the spasm is preferred to any attempt to force the tip between the cords. If Lidocaine is used, the tube should be left in place at least three to four hours until the protective reflexes of the larynx have recovered. The intubation procedure should not take more than 30 seconds.

Securing the Endotracheal Tube

For long term use, the endotracheal tube should be firmly secured to maintain proper position of the tip, to minimize functional stress from movements of the tube with each respiratory thrust and to reduce risk of accidental extubation.

Cover the eyes, paint the upper lip and cheeks with tincture of Benzoin. Allow to dry. Apply a butterfly of elastoplast cut to fit the face of the child. The wings of the butterfly should not extend over the lower eyelids nor should the crossbar be any wider than the upper lip. All edges should be within the area painted with Benzoin (Figure 3).

With the tube held in proper position, place a 4-0 silk suture in the wall of the tube at the level of the upper lip. Avoid obstructing the ET tube lumen with the suture stitch (Figure 4).

Tie, then wrap the suture around the tube and tie again. This prevents tension on the suture from cutting through the wall of the ET tube.

Next make a stitch in the elastoplast adjacent to the tube and tie firmly. Take another stitch about 1 cm away from the first; tie; wrap suture around the tube and tie once more. In tying the stitches into the elastoplast, pull snugly to fix the

be against that point of the upper lip. Clip the tracheal suture end. Further stability is added by using adhesive strips of tape three-eighths inch wide and three to four inches long, torn to within one inch of the end.

Place the broad portion of tape on the cheek and lip so that the crotch of the tear comes just directly at the suture point of the endotracheal tube. Begin the wind up around the ET tube at

the level of the suture in the tube. Make a smooth firm wrap with one strip and, beginning at the same level, wrap the other strip in the opposite direction. Do not cover the adapter rim with tape. A similar strip is applied from the opposite side (Figure 5).

Retaping may be necessary as secretions loosen the tape. The elastoplast and suture should stay for several days without need for replacement.

It is a common effect of low spirits or melancholy, to make those who are afflicted with it imagine that they are actually suffering those evils which happen to be most strongly presented to their minds. Some have fancied themselves to be deprived of the use of their limbs, some to labour under acute diseases, others to be in extreme poverty; when, in truth, there was not the least reality in any of the suppositions; so that when the vapours were dispelled, they were convinced of the delusion. To Johnson, whose supreme enjoyment was the exercise of his reason, the disturbance or obscuration of that faculty was the evil most to be dreaded. Insanity, therefore, was the object of his most dismal apprehension; and he fancied himself seized by it, or approaching to it, at the very time when he was giving proofs of a more than ordinary soundness and vigour of judgment.*

Historic Hospitals

Decline of the Arab Hospitals

Bonaparte Visiting the Pest-Ridden of Jaffa, by Baron Antoine Jean Gros. (Courtesy, Museum of Fine Arts, Boston.)

The maristans or hospitals which the Arabs developed from the ninth to the thirteenth centuries shared in the vigor of the period's civilization and participated in its decline thereafter. Since the hospitals depended upon their endowment properties or *waqfs* for support, they were particularly vulnerable to any adversities such as commercial reverses, destruction by warfare, or loss through embezzlement which diminished the value of their holdings.

By the end of the seventeenth century the resources of the last of the maristans were exhausted. Affairs at the once-proud Maristan of Qalaun at Cairo were deplorable. The specialists, pharmacists, and musicians, for which the hospital had formerly been famous, were now gone along with the generous daily allowance for each patient. The sick were left to recover as best they could.

Napoleon's Surgeon-General inspected the hospital in 1798 and found only twenty-seven sick patients, mostly victims of cancer, and fourteen insane confined in chains. Furnishings were limited to twenty-five wooden beds plus fifty stone slabs with holes in their centers for those incapable of walking to the latrine. The patients' diet consisted of bread, rice, and lentils.

Later in his Egyptian campaign Napoleon visited some of his plague-ridden troops being cared for in the hospital at Jaffa. The misery of the soldiers and the inadequacy of the hospital have been recorded by Antoine Gros in his well-known painting now owned by the Museum of Fine Arts in Boston.

The last to describe the operation of the Maristan of Qalaun was Edward W. Lane who visited there in 1847. Lane found the place being used for the confinement of the insane in cells, "each about seven or eight feet square, with a grated window." Shortly after his visit the Maristan ceased to be a hospital, the patients being transferred to the Mosque of Ibn Tulun.

Alcoholism

Why Do Alcoholics Deny Their Problem?

JON R. WEINBERG, Ph.D.*

THE DENIAL SYSTEM of a person with alcoholism is notoriously well-known to anyone with even a passing acquaintance with the problem. The individual will not accurately report the quantity and frequency of alcohol consumption. The adverse behavioral consequences of drinking will be minimized, explained away, or denied completely. For example, violent fights with a spouse may be described as minor arguments, or explained as due to the mate's bad temper, or simply ignored altogether. From the standpoint of the helping professional or friend or relative, the alcoholic's denial is usually perceived as lying, a transparent ploy to escape responsibility for his harmful actions. The result most often is hostility, as people generally have an intense dislike for lying and irresponsibility in others. This paper is intended to help clarify the factors which produce and maintain the denial system, so that others may react helpfully rather than rejecting the alcoholic.

Three components may be identified as critical in generating the denial system, all of which are interdependent and interact with one another to maximize their impact. For convenience, however, they will be discussed separately under the headings Cultural History, Social Environment, and Intrapyschic Consistency.

Cultural History

Alcoholic behavior has been described throughout recorded history. As with mental illness, the rationale used by people over the centuries to explain grossly inappropriate behavior involved possession by demons (including demon rum) or similar forces of evil. The problem was then dealt with by punishing the individual whose mind was possessed. The nineteenth century saw the beginning of a shift in attitude toward those called insane, but to this day a social stigma is clearly evident for this group. The problem with alcoholism

is still more complex as a function of the enormous cultural ambivalence toward drinking. One of the dominant institutions of our society, organized religion, has influenced us so powerfully against alcohol as an evil that this century saw a successful attempt to legally proscribe its use on a national scale. The failure of Prohibition reflects the eternally continuing importance people attach to using mood-altering chemicals.

The great majority of people today do use alcoholic beverages and are culturally endorsed for doing so in their own peer group and by the enormous mass media pressure exerted by the liquor industry. At the same time, our history is one of applying a powerful moral and social stigma to those whose drinking produces sufficiently undesirable behavior to lead to the label "alcoholic." In short, we reinforce drinking but vilify victims of alcoholism. In spite of a few decades of trying to shift social attitudes from a view of the alcoholic as "an evil person who should be punished" to "a sick person who should be treated," this transition has barely begun. The mentally ill have a century advantage over alcoholics in this respect and are by no means free of stigma. (Note that wealthy people who act crazy are usually sent to a "rest farm" in the country or a general hospital to recuperate from a "nervous breakdown" or from "overwork," while the poor end up in state hospitals labelled schizophrenic).

In brief, alcoholics have historically been regarded as being evil, morally and/or mentally inferior, and thus subject to social punishments—disapproval, rejection, ostracism. Who wants to be placed in the category "alcoholic"? Nobody! This is how cultural factors set the stage for denial.

Social Environment

The section above noted that drinking is a highly prevalent behavior in our society, with the combination of social custom and advertising glamourizing alcohol use as an essential part of "the good life." For most people, drinking is a

*Director of Training and Education, Hennepin County Alcoholism & Inebriety Program; Clinical Assistant Professor of psychiatry, University of Minnesota; and Private Practice. See editorial, page 691.

generally harmless activity secondary to various social occasions. For perhaps 8% to 10% of those who drink, however, alcohol use slowly shifts from a harmless to a harmful activity. The person's behavior gradually becomes increasingly inappropriate to the occasion. For example, a holiday gathering of a large family may be spoiled by his loud tirade directed at a sibling for some alleged old injustice. Perhaps an embarrassing scene occurs at a neighborhood party when she propositions her best friend's husband in front of everyone. Or again, he has the boss over to dinner hoping to win a promotion and ends up by telling him exactly where to go.

What will be the normal consequences of the undesirable behaviors cited? The answer is either *nothing at all* or at worst an admonishment the next day by the spouse. The latter may even suggest the desirability of drinking less, but the family or the friends and even the boss are very unlikely to say a single word to the individual (although they may be gossiping freely elsewhere). The budding alcoholic who may remember the incident fuzzily or not at all (a "blackout") is unlikely to accept the mate's version as accurate without other confirmation, and may impute her motives or otherwise rationalize it away. Faced with hostility from the drinker and lack of support from relevant others, the spouse most often takes the path of least resistance and resentfully tolerates the behavior. Worse, she may buy the common idea that his drinking is somehow caused by her inadequate behavior as a wife. She is even likely to cover up for him by making excuses for his behavior to others, e.g. telling the boss he's home sick with "flu" instead of a hangover. Thus reality is not being forcibly presented to the individual.

As adverse consequences of drinking gradually multiply, more people are introduced into the picture. A physician, marriage counselor, or clergyman may be consulted at the mate's insistence, after years of increasing family turmoil. What are the chances that alcoholism will be diagnosed and made a central focus? Minimal, as a function of inadequate training in alcoholism plus, often, systematic cultural biases against considering a person alcoholic until the late stages. Physicians may quietly suggest "cutting down" on drinking while writing a prescription for some other sedative drug which potentiates alcohol. Counselors may discuss "improving marital communication" and ignore the drinking as a "mere symptom." Clergy-

men may press for more regular church attendance and family togetherness. Here, "experts" are saying in effect that the problem is not alcoholism. Furthermore our social system is so structured that *the higher the income level the less probable alcoholism will be diagnosed.*

In summary, what are all the important people in his life, possibly excepting his mate, most often saying to the person with early-stage alcohol-related problems? *Nothing whatever about the harmfulness of his drinking.* They may be just plain ignorant about the early stages of alcoholism, believing alcoholics are winos in the gutter, never well-dressed businessmen and housewives; they may be too polite or too fearful of hostile reaction to discuss this socially embarrassing topic with the individual; or they may feel it's none of their business. The result of this innocent but deadly conspiracy of silence in the individual's social environment is to provide extremely fertile soil for denial of reality.

Intrapsychic Consistency

It appears to be a law of human behavior that two directly conflicting beliefs cannot co-exist for very long in one individual. As a person's drinking begins to produce adverse results, such a conflict is created. On the one hand, alcohol has become an important and rewarding component of his life. He likes to drink because it produces unusually good feelings and/or helps shut off bad feelings.¹ On the other hand, reality is relentlessly trying to impose awareness of impaired mate and family relations, work efficiency, etc. At this point there are only two possible resolutions of the conflict: reject drinking or reject reality. Some people do select the former, especially if he is one of the lucky few who has important people, such as family members or helping professionals, confronting him with the connection between drinking and undesirable reality. Many more, unfortunately, begin to reject reality, which is obviously the more likely alternative given the remarkable propensity of humans to rationalize whatever behavior they find highly rewarding.

Is the alibi system of the alcoholic really so different from that of the compulsive smoker who rejects the medical evidence for lung damage, the compulsive eater who says people like her better fat, the compulsive executive with heart disease who insists the corporation would collapse if he didn't put in 16-hour days? All of these people

have a specific delusion, a denial of reality, which serves the vital purpose of allowing the desired behavior to continue without overwhelming mental conflict. The primary reason people are sometimes more disturbed by the alcoholic's denial is that their behavior is relatively more harmful to other people, as opposed to being harmful only to himself (which probably also explains their higher recovery rate).

For the alcoholic, accepting reality is tantamount to working to maintain sobriety, and it is simply unreasonable to expect someone with a profound dependence on a substance to give it up without a struggle. The longer the history of dependence, the worse reality becomes, the more complete the denial must be, and the greater the struggle to modify the process. In the terminal stage, near death from cirrhosis, the alcoholic may deny any history of drinking whatever. Such pathetic outcomes can only be prevented by a widespread knowledge of the early symptoms of alcoholism² combined with a forceful confrontation with reality by all those deeply concerned with the developing alcoholic. In the early stages, such intervention will lead to a high proportion of successful outcomes.

Summary

The history of moral stigma associated with alcoholism provides the cultural context for denial. The tendency of family, friends, and helping professionals to avoid or overlook the issue in dealing with the alcoholic in the earlier stages provides the social environment which permits and encourages denial. The individual's normal tendency to avoid internal conflict fosters denial of unpleasant reality in order to permit the rewards of continued drinking. If the cultural attitudes toward alcoholism are successfully shifted to an illness-without-stigma model; and more importantly, if concerned persons are knowledgeable enough to see alcoholism developing *and* persistently confront the individual with reality; then far less problems will occur with the third, or individual, component. If the environmental reinforcements for denial are absent, the individual will have little opportunity to successfully generate a denial system. Until these changes occur, we will continue to be frustrated by the stubborn resistance to change of the advanced stage of denial most people associate with the illness of alcoholism.

Book Reviews

MEDICINE FOR THE PARAMEDICAL PROFESSIONS AND WORKBOOK FOR MEDICINE FOR THE PARAMEDICAL PROFESSIONS by Douglas W. Piper, Published by McGraw-Hill Book Company, Sydney, Australia, 1970.

Too many of the books designed for teaching the paramedical professions are devoted to either first aid or methods of transportation of the sick and wounded. This book provides a general review of medicine by organ system and is accompanied by a workbook with a programmed learning format.

The forward states that "to serve its purpose properly, a medical book must combine the readability of a current journal with the exactness and factuality of a reference book, and this is the aim of the group of young men who have combined to write this book." That the 38 authors succeeded is a tribute to the editors.

There are a few rough spots which will serve as minor annoyances—for example, Australian tradenames are used for many drugs and many of the abbreviations in the index are not explained in the text. Some Australian terminology also creeps in—for example, the use of the term morbilli instead of measles.

On the positive side, the color photographs in the dermatology section are excellent as are the illustrations.

I can recommend this book for teachers and students in the paramedical professions.

VASECTOMY, SEX & PARENTHOOD by Norman Fleishman and Peter L. Dixon, Doubleday & Company, Garden City, New York, 1973—\$5.95.

This small book has been written, if one will pardon the expression, by laymen for the layman. It is a good book for prospective vasectomy patients. Vasectomy is discussed in detail, and favorable testimonials are given by several patients, including the authors. A wife's attitude towards her husband's vasectomy is related.

One note of caution relates to the only significant error in the book. This occurs in the discussion of sperm banking. The author states that sperm banking provides "insurance" for the man who is undergoing vasectomy. Unfortunately, they are unaware that sperm banking is still experimental at best. Capability of sperm banks has not yet been well established, and results of recent studies* indicate viability of frozen sperm drops off rapidly after one to three years of storage. Thus, prospective vasectomy patients should probably not expect more than two or three years "insurance" from storage of

their sperm.

There is an important discussion of all of the wrong reasons for having children, and also a brief discussion of male machismo and what constitutes masculinity. All of this is related to serious concern about our overpopulated polluted world. The personal and social costs of unwanted and unplanned children are reviewed. All in all, it is a good book for individuals considering vasectomy or in the process of deciding whether they should have children. It will help couples gain insight into the unconscious reasons why people have children and the personal and social morality which now all but demands that a couple limit their reproduction to two children or less.

TEXTBOOK OF CORONARY CARE. Edited by Lawrence E. Meltzer and Arend J. Dunning. \$18.00. The Charles Press, Philadelphia. 1972. 820 pages.

Introduced only ten years ago, the coronary care unit has become an essential part of the therapy of patients with myocardial infarction. In addition, such developments as synchronized D. C. countershock, intravenous lidocaine, temporary and permanent transvenous pacemakers, and new surgical techniques have made the past decade a fruitful one in the treatment of coronary heart disease.

These topics and many others relating to coronary care are discussed in this book. In addition to the more accepted means of therapy, controversial topics are included, such as: Aortic balloon pumping in the management of cardiogenic shock, "Polarizing" solution, the resection of akinetic areas of myocardium ("infartectomy"). The editors have done a fine job in keeping the presentations brief but well-balanced and meaty. Duplication between authors is avoided. Particularly useful is a supplemental bibliography which includes references up to 1972.

This book will be of value to all who are involved in coronary care: physicians, students, and nurses. It should be on the bookshelf in the C.C.U. as well as in the medical library since it provides a wealth of practical information as well as more theoretical discussions. With the rapid development of new knowledge and techniques in this field it is likely that a new edition will be needed in a few years.

The Family Physician

A Comparative Study of Minnesota and Wisconsin Family Physicians Practicing in Rural and Urban Communities¹

SUSAN E. JOHNSON, M.A.,* WALTER L. BAEUMLER, PH.D.† and
ROBERT E. CARTER, M.D.*

THE NEW UNIVERSITY OF MINNESOTA, Duluth, School of Medicine has identified as one of its special missions study of the educational process for family practice, particularly in rural areas of the upper midwest. This goal places the School of Medicine somewhat in opposition to the nationwide social and economic trends toward specialization and urbanization dominating the structure of medical practice. An institution committed to such purposes must examine special means it will employ in moving toward its goal. As one aspect of the Duluth School of Medicine's evaluation of new educational methods, the commitment was made to study certain behavioral and attitudinal characteristics of currently practicing rural and urban general practitioners as well as urban specialists.

The study herein reported in part was thus motivated by both a practical and a theoretical interest. The practical interest has to do with the School of Medicine's desire to maximize the probability that physicians receiving their initial training would indeed choose rural family practice as their final career choice. The assumption underlying the study was that variables characterizing present practitioners might prove useful in both the selection and socialization (training) of future practitioners.

This report presents the comparison of rural and urban general (family) practitioners. The comparison of rural and urban general practitioners with urban specialists will be presented in a second paper.

The present study contributes to the growing empirical literature exploring the relationship between medical practice locales and styles of medical practice.² This literature suggests the same

general conclusions as the present study: rural and urban physicians differ little in certain conditions of medical practice they experience. The difference between them emerges in the experiences of living within the social structure of a small community for the former, in a metropolitan community for the latter.

Methodology

Sixty rural general practitioners (RGPs) in the eleven northeastern Minnesota counties (40 respondents) and the ten northwestern Wisconsin counties (20 respondents) were interviewed during the summer and fall of 1971. A comparative sample of 58 urban general practitioners (UGPs) in Duluth (20 respondents) and Minneapolis and St. Paul (38 respondents), Minnesota, were interviewed in the fall of 1971. Both samples were randomly chosen from among the physicians who identify themselves as general practitioners in the American Medical Association's *Directory of Physicians, 1969*. The rural sample was drawn from towns with a population of 10,000 or less; the urban sample from cities of 100,000 population or more.

Both samples were stratified by age to assure the selection of younger doctors in the same proportion as their representation in the population and by number of physicians (including the respondent) practicing in the community, as this was thought to represent significantly different practice conditions. The interview required approximately one hour of each respondent's time to complete. More than 300 separate items explored various aspects of the physicians' life experiences, professional experiences, and attitudes. Items in the study found to reveal significant differences between the two samples are reported and discussed here. The chi-square test was used for analyzing the differences among nom-

See editorial, page 689.

inal items and a five percent level of significance was used to separate differences not attributable to chance association.³

An educational institution can have an impact on the career choices of its graduates through two methods, selection of those most likely to work toward the specified outcomes and training of those chosen to a realistic appreciation of the demands of their possible professional role. The study was designed to explore material relevant to both selection and training. This report is thus presented in two complementary frameworks: (1) significant differences between RGPs and UGPs which might be applicable to selection policies of any medical school and (2) significant differences between RGPs and UGPs relevant to realistic training of students to the role of the family physician practicing in a rural setting.

Characteristics of the Sample

The tabulation of physicians' responses to demographic and practice questions is reported in Table 1. The great majority of both rural and urban physicians interviewed were male and married. The distribution of age for the two samples was remarkably similar. Slightly under one-half were between 41 and 60 years old, approximately one-quarter were 40 years old or younger and one-quarter 61 years old and older.

The distribution of respondents according to number of physicians practicing in the community reflects the study design. All urban respondents were drawn from cities of 100,000 population or more, a situation essentially guaranteeing that 100 or more physicians will practice in the community. The rural respondents were selected in such a way that the sample distribution of approximately 20 percent in communities with three physicians or less and 40 percent in communities with four physicians or more reflects the actual distribution of rural physicians in the universe as a whole. Slightly over half of the rural physicians practiced in towns with a population between 1000 and 5000. One third practiced in towns between 5000 and 10,000 population, and 13 percent practiced in the smallest communities, less than 1000 population.

The sampling of practice structures showed that slightly more urban than rural family physicians have solo practices (not a statistically significant difference). Approximately one-fifth of both groups practiced in a two-physician partnership, while half or more of each group practiced in groups of three or more.

Results Relevant to Selection Procedures

Both the rural and urban family physician samples were overwhelmingly *male* (98.3 percent and

93.1 percent, respectively) and *married* (93.3 percent and 86.2 percent). The randomly-selected samples contained no blacks or Indians. Indeed none were found among the family physicians in the study area.

When asked their attitudes about whether or not a prospective general practitioner should be male and married,⁴ urban general practitioners felt less strongly about maintaining the status quo; a majority of them in each case indicated that a new doctor entering a practice such as theirs "may or may not" possess these attributes.⁵ A slight majority of the rural general practitioners (56.7%) felt a doctor "preferably should" be married, and 45% stated such a doctor should be male. The difference between RGP and UGP attitudes on physician marital status was significant at the 0.05 level. Majorities in both groups felt a doctor need not be white.

More significant differences were found when we looked at selected life experiences of the two groups.

The cluster of variables most closely associated with rural rather than urban general practice was the *size of the community of origin* of the doctor. Doctors who practiced in communities of less than 10,000 population were far more likely to have grown up in such communities than are doctors practicing in cities of 100,000 population or more ($X^2 = 19.5$; $df = 1$; $p < 0.001$). As shown in Table 2, this relationship holds true when doctors were asked about the size of community in which they spent their *pre-school years*, their *primary school years*, and their *secondary school years*. The increasingly rigorous levels of significance suggest that this difference becomes more evident as age of the youngster increases. The interpretation can be offered—though longitudinal data would be needed to demonstrate it—that the longer the young person who will become a doctor remains in his small community, the more likely he will be to return to such a small community to practice.

No significant differences were found between rural and urban family physicians with respect to the *geographical location of their community of origin*. Equal percentages of rural and urban general practitioners came from Minnesota and Wisconsin (60% and 65%), from other upper mid-west states (11.7% and 3.4%), and from other states or foreign countries (21.7% and 20.6%).

The respondents' *attitudes* toward items deal-

ing with size of community of origin also showed significant differences. Rural general practitioners were more likely to value a new doctor with a rural or small town background and to discourage a new doctor with a city background. Neither group found it important that a new doctor be a native of this region (80% of RGPs and 74.1% of UGPs responded "may or may not.") (Table 3).

TABLE 2

	Neutral or Preferably Should	Preferably Should Not
Preference for Large City Background		
RGPs	38	22
UGPs	54	0

The size of the community of origin is also significant when the *spouse's community of origin* is explored. As Table 4 demonstrates, RGPs' wives are more likely to have come from towns of under 10,000 population.

TABLE 4
Size of Community of Origin of Physicians' Wives
Size of Community

	Less than 10,000	More than 10,000
RGPs	32	21
UGPs	11	38
$x^2 = 15.0$; $df = 1$; $p < 0.001$		

No significant differences between RGPs and UGPs were found with respect to *father's education*. Though UGPs' fathers had slightly more education up through high school, more RGPs' fathers in our sample had some college or professional training after high school. Twenty-three percent of RGPs' fathers and 24% of UGPs' fathers were college graduates or had postgraduate training. The pattern for *mother's education* is similar and also shows no significant difference between RGPs and UGPs. Fifteen percent of RGPs' and 10.3% of UGPs' mothers graduated from college or had post-graduate training. This is in sharp contrast with findings in the urban specialists group to be reported subsequently.

Differences in *father's occupation* were significant. RGPs are far more likely to have fathers who were farmers or blue collar workers; UGPs, fathers who were white collar workers. When the full array of occupational categories is examined, UGPs' fathers were more often professionals or white collar workers, while RGPs' fathers were more likely to be farmers or skilled workers ($\chi^2 = 14.0$; $df = 6$; $p < 0.05$). Whether or not the father's occupation was health-related did not differentiate between our two groups. Nor did either *mother's occupation* or *mother's occupation health-related*.

RGPs	29	28
UGPs	40	12
$\chi^2 = 8.0$; $df = 1$; $p < 0.005$		

Results Relevant to Socialization Factors

The doctors were asked what factors were most important in their decision to establish a practice in the community they chose. More UGPs than RGPs said the *most significant factor in choice of practice community* was either that they were born or raised in that community or held an internship, preceptorship, or residency in the community. RGPs are more likely to mention particular geographical features of the community, its climate and recreational opportunities or medically-related features, such as particular facilities or practice structures ($\chi^2 = 18.0$; $df = 5$; $p < 0.01$).

The large size of the UGPs' practice sites makes it more likely that they would have been born in the same city where they now practice and that they could have held an internship or residency

there. Indeed, more UGPs than RGPs received their internship training in Minnesota or Wisconsin, while nearly half the RGPs received this training in another state (33.3%) or another upper midwest state (10%; $\chi^2 = 8.8$; $df = 2$; $p < 0.05$).

The RGPs, on the other hand, though born in a town much the size of their own, are oriented more to a geographical region than a particular city. They also found access to particular medical facilities more salient than did UGPs who had available to them the larger range of facilities and structures within a metropolitan area.

The importance of geography, climate, and recreation to the RGPs was also apparent in their attitudes toward a related item. RGPs were far more likely to advocate a new doctor being interested in *outdoor recreation* (58.3% said preferably should; 3.3%, absolutely must) than were UGPs (15.5% said preferably; none responded absolutely must; $\chi^2 = 24.9$; $df = 2$; $p < 0.001$).

The assumption that the styles of medical practice of rural and urban physicians differ substantially was *not* borne out in the study. Rural and urban general practitioners did not differ significantly with respect to most of the professionally oriented variables that were explored.⁶ No statistically significant differences were found in *structure of practice*, *number and quality of support personnel*, *adequacy of medical facilities*, *income*, or *income discrepancies* between these doctors and specialists, *job satisfaction*, *family satisfaction*, *degree of worry*, *proportion of time spent on house calls*, or *length of vacations*. Nor did the doctors' attitudes toward medically related attributes or behavior differ significantly.

Two aspects of RGP and UGP professional practice were interesting. These have to do with *time demands* and *referrals*. RGPs worked longer hours than UGPs. Over half the RGPs (56.7%) estimate they worked between 60 and 80 hours per week, while 36.2% of UGPs do so. Fifty percent of UGPs worked between 40 and 60 hours per week. Only 31.7% of RGPs do so. Thus, although both groups worked long hours, higher time demands were made on RGPs. Also, RGPs saw more patients in their working day, either in their offices or on hospital rounds, than did UGPs. Nearly one-quarter of RGPs saw between 50 and 70 patients per day, while only 5% of UGPs saw this many patients. The mode for both groups was between 30 and 50 patients per day.

A reflection of this differing work load is found in the doctors' attitudes toward *schedules* of hospital rounds and office appointments in their practice. A plurality of RGPs say a doctor preferably should be flexible (not attempt to maintain exact schedules) while a plurality of UGPs said he preferably should maintain exact schedules ($\chi^2 = 15.6$; $df = 4$; $p < 0.01$).

A statistically significant difference in the two group's styles of practice had to do with their *need for referrals*. A majority of both groups found they need to refer fewer than 10% of their cases to specialists. However, over three-quarters of RGPs refer this small proportion of cases, while 50% of UGPs do so. About one-third of UGPs refer between 10 and 25% of their cases, while only 16.7% of RGPs refer this many cases.

TABLE 6
Physicians' Perceptions of Frequency of Referrals
Proportion of cases which need
to be referred

	Less than 10 per cent	More than 10 per cent
RGPs	47	10
UGPs	30	22

$\chi^2 = 7.95$; $df = 1$; $p < 0.005$

This pattern of referrals appeared to reflect comparative isolation of RGPs and thus the emphasis in their practice on handling relatively more problems locally. In open-ended responses, rural physicians emphasized the importance of training students to handle emergencies, to rely on themselves, to know what they can and cannot do, to develop self-confidence in their abilities, to realize that they and they alone will often be faced with the unexpected, yet will be expected to handle it.

With the sole exception of these referral patterns and certain time demands, rural and urban general practice attitudes and conditions appeared to differ little. The real differences between small town and big city general practice had to do instead with the nature of life in a small town. Many significant differences were found between the attitudes of the rural and urban respondents with respect to behavior desirable of a new doctor in the community.

Most urban respondents answered "may or may not" to the items discussed below. The rural respondents, however, felt a new doctor preferably should be a *homeowner*, *spend his money in the community*, *attend school or athletic activities of his children*, *have his wife be active in the com-*

munity, *lecture to school or community groups*, and *hire his staff from the local community*.

Several items related to community life were more salient for these rural physicians, as evidenced by the fact that they did not agree on the proper way to handle them. The issue of whether or not a doctor should be an *active member of a political party* was more salient for the RGPs, significant minorities of whom felt either that a doctor preferably should or that he preferably should not be an active member. UGPs again said may or may not ($\chi^2 = 6.3$; $df = 2$; $p < 0.05$). Nearly 40% of UGPs said a doctor may or may not keep a watchful eye on the *personal lives of his staff*. Less than one-quarter of the RGPs (23.3%) were this neutral about the issue. Fifty percent of them said a doctor preferably should not or absolutely must not keep a watchful eye, but 23% said he preferably should or absolutely must. RGPs are also more ambivalent about whether or not a doctor should *counsel patients about non-medical matters*. Only 12% of RGPs are neutral about this issue, 60% of them believing a doctor should or must do so, 28.3% saying he should not or must not. Seventy percent of UGPs are neutral or say he preferably should.

Thus, various aspects of the on-going life of the community are regarded as more critical and problematic factors by the rural than the urban general practitioners.

The patterns of the doctors' friendships also indicate the degree to which rural behavior is molded by the nature of the community. The doctors were asked to report the *occupation of their best friend in the community*. Sixty-three point eight percent of the urban doctors named another professional as their best friend, while only 38.3% of rural doctors did so. Twenty-five percent of rural doctors named a friend in the managerial, proprietor, or official occupational category, while only 3.4% of urban doctors named such a person ($\chi^2 = 14.110$; $df = 3$; significant at .01 level). Thus, though among both groups professional friends are important, a large number of rural doctors also develop their most significant friendships with local store owners and managers, the people they do business with every day.

Summary

The variables which most clearly differentiated rural and urban family physicians had to do primarily with their differing degrees of prior expe-

rience with rural or small town communities and their differing degrees of present involvement in the life of their community.

The significantly different *selection variables* demonstrate that rural family physicians were more likely than urban family physicians to: (1) come from a small town or rural area, (2) have wives who also came from a small town or rural area, (3) believed such a background is important, (4) chose their practice site because of particular geographical or medically related features it offered, and (5) believed an appreciation of the outdoors is important. In addition, rural physicians were more likely⁶ to have fathers who were farmers or blue collar workers.

The significantly different *socialization variables* revealed that rural family physicians differed from urban family physicians in that they: (1) worked longer hours and saw more patients, (2) referred fewer patients to specialists, (3) found keeping to rigid schedules more difficult and less essential to perform their role, (4) felt it was important to involve themselves in the community in many direct and personal ways.

The rural physicians seemed more concerned than their urban counterparts about whether or not a doctor should be an active member of a political party, watch over the personal lives of his staff, and counsel patients about non-medical matters. Lastly, rural family physicians were more likely than urban family physicians to have their closest friend in the community a non-professional person.

What appeared to distinguish rural from urban family physicians—and what perhaps may apply to selection and socialization of students for rural general practice—were not differences in attributed characteristics or conditions of medical practice. Rather, it was the individual's experience with and understanding of the nature of life in a small community, a life the rural physician intimately shares with his neighbors.

A major portion of this study was made possible through the generous support of the Peavey Company of Minneapolis, Minnesota as part of their continuing interest in improving the quality of life in the smaller communities of the upper midwest.

Notes

1. This is the first report of a projected series of comparative studies underway at the University of Minnesota, Duluth, School of Medicine which will explore the attitudes and behaviors of groups whose members play significant but different roles in the health care system. Groups to be studied in the future include physician specialists, naive and informed consumers, and patients. Such a long-term study involves the considerable efforts of many people whose degree of responsibility for any particular aspect of the study is not well reflected in the limited status of "authorship." The authors of this particular phase would thus like to acknowledge their indebtedness to Caryl B. Bentley and Wayland R. Swain, School of Medicine; Philip C. Campbell, Department of Sociology; and John Blair, Department of Sociology, University of Michigan. In addition, appreciation is due the other members of the faculties of the School of Medicine and Department of Sociology, all of whom contributed in some important way to the study.
2. Special thanks are given to the Minnesota and Wisconsin physicians who shared generously with us their time and thoughts and to Dr. E. P. Donatelle, President, Minnesota Academy of General Practice, and Dr. George V. Murphy, President, Wisconsin Academy of General Practice, for their support and encouragement.
3. For example, see Breu, TM: Geographical and Professional Characteristics of Illinois Health Manpower—Distributional Factors and Determinants, Southern Illinois University, unpublished doctoral dissertation, August, 1972; Hassinger, EW: Background and Community Orientation of Rural Physicians Compared with Metropolitan Physicians in Missouri. Research Bulletin Number 822, University of Missouri College of Agriculture, August, 1963; and Parker, RC and Tuxill, TG: The Attitudes of Physicians Toward Small Community Practice. JME 42:327-344, April, 1967.
4. When responding to such attitudinal items, the physician respondent can be interpreted as playing a dual role: that of subject, in which case his responses indicate the climate of opinion within which new family physicians would operate; and, that of informant, in which case his responses advocate various policy considerations.
5. Attitude questions were phrased: "Suppose you wanted to leave your practice in this community. What kind of doctor would you recommend should take your place? Should this person be . . . ?" Possible responses were: "Absolutely Must, Preferably Should Not, Absolutely Must Not." The form for such attitude items is adapted from Gross, N, Mason, and McEachern, A. Explorations in Role Analysis. John Wiley and Sons, 1958.
6. A 1963 study of rural/urban physician differences in Missouri confirms this finding. One of the author's principal conclusions is that, "practice in the rural area is not so different, in terms of technology available, from practice in the city." Hassinger, *op. cit.*, p. 83. Further, the author finds no differences between rural and urban physicians in memberships on hospital staffs, working relationships with other physicians, or membership and participation in professional organizations. *Ibid.*, p. 105.
7. See the occupational categories in Lipset, SM and Bendix, R. Social Mobility in Industrial Society, University of California Press, 1964, p. 50; and in Barber, B. Social Stratification. Harcourt, Brace and World, 1957, p. 174. The category system used in the present study is an adaptation of these two scales.

Minnesota-Dakota-Manitoba Orthopaedic Society

Minnesota-Dakota-Manitoba Orthopaedic Society, 49th Annual Meeting, September 14 and 15, Sioux Falls, S.D. For information about membership and all other questions contact Ed Kelly, Min-Da-Man Central Office, 120 North Snelling, St. Paul, Minn. 55104. Phone: 612-646-2533. All board eligible and board certified orthopaedists in this area are welcome to be members. Place: Holiday Inn Downtown, 100 W. 8th St., Sioux Falls, S.D. 57102. Scientific Program: Begins 1 p.m. Sept. 14.

In Memoriam

WALTER R. RAMSEY, M.D.

Dr. Walter Reeve Ramsey, 100, one of the first pediatricians in St. Paul and the founder of Children's Hospital in St. Paul, died March 11. He was born on a farm near Rockwood, Ontario, went to college in Guelph, Ontario, and came to Duluth when he was 21 years old. Later in 1893 he entered the University of Minnesota Medical School and received a doctor's degree in 1896. Later he studied at Johns Hopkins and in Vienna and Berlin.

During World War I, he served in France and his work for children brought him honors from the French government. In Rouen, France, he was instrumental in the establishment of a children's hospital, a maternity hospital and an orphanage. It was while he was on a European trip that he visited the famous Dr. Rollier's Children's Hospital in the Alps which was his inspiration for founding the Children's Hospital in St. Paul.

He was a member of the American Medical Association and the Ramsey County Medical Society and a 50 Club and Associate Member of the Minnesota State Medical Association.

Dr. Ramsey is survived by his son, W. Reeve Ramsey.

HAROLD S. DIEHL, M.D.

Dr. Harold S. Diehl, dean of the University of Minnesota College of Medical Sciences for 23 years and chief medical officer of the American Cancer Society for 10 years, died June 27 in St. Paul at the age of 81.

Born in Nittany, Pa., in 1891, Dr. Diehl entered the University of Minnesota Medical School in 1914. After graduation he served as an intern and physician with the armed forces in France and after World War I he was on the Red Cross staff in Poland.

In 1921 he returned to the University to direct the Student Health Service. He also organized the first department of preventive medicine and public health in the Medical School a year later. Dr. Diehl was one of the organizers of the American Student Health Association, serving as president from 1927 to 1929.

During this period he initiated tuberculosis control through a mandatory tuberculin test for all students entering the University.

Upon his retirement as dean in 1958 he became the senior vice president for research and medical affairs and deputy executive vice president of the American Cancer Society (ACS).

Dr. Diehl was actively involved in many professional organizations and authored more than 200 scientific papers and several books, including a new edition of his popular textbook "Healthful Living" just re-released by

McGraw Hill. First published in 1935, the book was one of the first health books widely used at universities and colleges in this country. He was a member of the Hennepin County Medical Society, the American Medical Association and a 50 Club and Life Member of the Minnesota State Medical Association.

Dr. Diehl is survived by a son, Dr. Antoni Diehl of Kansas City and a daughter, Annabelle.

ADAM M. SMITH, M.D.

Dr. Adam M. Smith, 79, Minneapolis internist, died May 31. Born in Minneapolis, Dr. Smith graduated from the University of Minnesota Medical School and interned at Minneapolis General Hospital.

A former Associate Clinical Professor of Medicine at the University of Minnesota, Dr. Smith was also a member of the Hennepin County Medical Society and the American Medical Association, and a 50 Club and Life Member of the Minnesota State Medical Association.

In 1938 he spoke before the Third International Goiter Conference in Washington and described the successful treatment of exophthalmic goiters by deep X-ray.

Dr. Smith is survived by his wife, Helen, and son, Dr. Alan G. Smith of New York.

OTTO BERGAN, M.D.

Dr. Otto Bergan, 89, Clinton physician, died May 1. Born in Rock Dell, Minnesota, and educated at the University of Minnesota Medical School, Dr. Bergan began his medical practice in Clinton in 1914.

He was a member of the West Central Minnesota Medical Society and the American Medical Association, served on the boards of both the Ortonville and Graceville hospitals, and was a Life and 50 Club Member of the Minnesota State Medical Association.

Dr. Bergan is survived by his wife, Cora, and two sons, Dr. Donald Bergan of Fargo and Dr. Robert Bergan of Duluth.

ELMER H. HARTUNG, M.D.

Dr. Elmer H. Hartung, 63, medical practitioner in Claremont for the past 39 years, died May 6. He was born in LeSueur and moved to St. Paul at the age of 14. A graduate of the University of Minnesota Medical School, Dr. Hartung also served several years as the Dodge County Health Officer.

He was a member of the Steele County Medical Society, the American Medical Association and the Minnesota State Medical Association.

Dr. Hartung is survived by his wife, Beth, and two sons, Brian and Donald.

RIVERS EDGE MEDICAL CLINIC—Farmington, Mn. needs two additional General Practitioners to practice in a nearly new Clinic, Hospital and Nursing Home. Fast growing area just 45 minutes from St. Paul-Minneapolis. Metropolitan advantage with Community living. Contact M. H. Hunter, M.D. (612) 463-7181.

EXPANDING TEN MAN FAMILY PRACTICE GROUP in southern Minnesota. Seeks **GENERAL PRACTITIONER OR INTERNIST** for summer of 74. New clinic adjacent to a new 114 bed hospital. Fairmont is a progressive community (City of Five Lakes). Starting salary open, early partnership opportunity. Contact D. E. Grandgenett, Fairmont Medical Clinic. 507-238-4263.

WANTED—General Practitioner for an incorporated practice. Wisconsin community of 6,800 on interstate highways. Excellent schools, recreational facilities. Modern clinic adjacent 85 bed hospital. Salary first year then partnership. Call 608-372-4177 Collect.

HELP—us form 3 to 4 man group. 60 bed new hospital. Resident anesthetist, physiotherapist. County seat and industrial town. Modern clinic facilities. Supreme fishing-hunting close by. Artificial ice arena. Municipal pool and golf course. Shared education and vacation time. Good deal! Drs. Delmore and Metcalf, Roseau, Minnesota 56751.

G. P. AUSTIN desires an associate. Partner retiring Florida. \$25,000 salary first year. Partnership after one year. 165 bed hospital. Close to Minneapolis and Rochester. Write: Joseph Mlinar, M.D., 605 N. Main, Austin 55912.

COUNTRY LIVING-METROPOLITAN CONVENIENCE—WANTED AND NEEDED: One or two General Practitioners to set up practice in new and equipped clinic with utilities paid and rent free 6-12 months. Service area of 9,000 and rapidly growing. New hospital in planning stages, new high school under construction. Located within one hour of Minneapolis-St. Paul. Dental, Veterinary, and Mental Health Clinics also located here. Golfing, bowling, fishing, hunting, etc. in area. Interview expenses and all moving expenses paid. Join us for comfortable country living with big city benefits. Try it, you'll like it! Write: **MINNESOTA MEDICINE**—485, 375 Jackson, St. Paul 55101.

A BETTER PLACE TO PRACTICE MEDICINE

For those who would prefer to live in a warmer climate, avoid the big city school, traffic and practice problems; contact this multi-specialty group located in a city of 100,000 people in North Central Texas. Specialists in Internal Medicine, Family Practice, Pediatrics, General and Orthopedic Surgery are needed to complement the current staff of twenty-one full time physicians. Wichita Falls Clinic-Hospital, 1300 Eighth, Wichita Falls, Texas 76301.

GENERAL PRACTITIONER desired for northern Minnesota clinic located near Lake of the Woods area. Enjoy the clean air, clear waters, compatible working arrangements including ample time off for meetings, vacations and good financial arrangements. Excellently equipped hospital (acute, skilled nursing and board and care facilities.) fine clinic one block from hospital. Write: Minnesota Medicine, 473, 375 Jackson St., St. Paul 55101.

WAYZATA MEDICAL BUILDING OFFICE SUITES—Located in the fastest growing suburban area in the Twin Cities. We offer:

- Surrounding area of lakes, country clubs, woods, beautiful homes;
- Unsurpassed medical building facilities
- Fast growing area—high median family incomes
- Beautiful building—inside and out
- Inner courtyard with trees and landscaping
- Heated indoor parking
- Adjacent access to freeway system
- Low rental rates—favorable base terms
- Financial services

We have grown to fourteen specialties since our building was completed two years ago. We particularly are interested in Orthopedics, Psychiatry, Urology, Otolaryngology, Internal Medicine and Dentistry. Give us a call. We have a lot more to show you and to talk about. Reply to: Mr. Paske, Wayzata Medical Building, 250 North Central Avenue, Wayzata, Minn. 55391, (612) 473-0031.

INTERNIST wanted to join Six-man Department in twenty-two man multi-specialty group. Growing incorporated practice; nearly new Clinic facilities; full range of fringe benefits, including profit sharing fund participation and generous time-off allowance; equal shareholder at end of one year; salary first year, incentive pay plan thereafter. City of 35,000 with excellent schools and colleges; fine residential areas for family living; 1½ hours to Twin Cities; much recreational and cultural activity available locally. Great place to live and practice. Call collect or write C. H. Brady, Jr., M.D., Mankato Clinic, Ltd., Mankato, Minn. 56001. (Telephone 507-387-1811).

Classified Advertisements

GENERAL SURGEON AND INTERNIST needed to join expanding 5-man group. Approximately 4,000 patients per month keeps all extremely busy. Located in the heart of the pines and lakes in growing Northern Minnesota community serving area of 35,000. Community features excellent medical facilities, stable diversified economy, year-round recreation and cultural center, and pleasant family environment. Starting salary \$30,000-plus depending on training and experience, all fringes including IRS-approved pension plan. We invite you to call or write us for more information. K. H. Stolen, M.D. or T. R. Brill, Administrator, Box L, Grand Rapids, Minnesota 55744; or call 218-326-6613 (day) or 218-326-5447 (evenings).

FAMILY PRACTITIONER WANTED to join small progressive group serving beautiful Mille Lacs Lake area, only eighty miles north of Minneapolis. Modern clinic and JCAH seventy-three bed hospital and ECF. Excellent income potential; group support, two out of three weekends off. Away from the madding crowd; yet not too far away. Good schools; clean, uncrowded environment; lakes to live on; unfettered living. We need you. Contact: Dr. Dennis R. Jacobson, 612-532-3113 (clinic), 612-532-3628 (home), or Marshall E. Engstrom, Hospital Administrator, Community Mercy Hospital, Onamia, Mn. 56359. 612-532-3154 (office), 612-532-3693 (home).

PART OR FULL TIME, Southdale or downtown Mpls., GP or internist. Pleasant work, mainly examining executive and professional people, no weekend or evening duty. \$20 per hour part-time or \$30,000 annually full time. Free time easily arranged for outside activities or extra vacations on pro rata income basis. Special arrangements can be made for physical handicaps other than age (62 is the upper limit) or sensory loss. Must be graduate of U.S. school licensed or licensable in Minnesota. Write: MINNESOTA MEDICINE—484, 375 Jackson, St. Paul 55101.

SHELL LAKE CLINIC, LTD., Shell Lake, Wisconsin, expanding to seven man group. Three family physicians and one surgeon desire additional two family physicians and one internist. New 70 bed general hospital adjoins clinic. Excellent remuneration in corporate practice. City surrounds one of largest and finest swimming and fishing lakes in Northwest Wisconsin. Call 715-468-2711 or write to Clinic Manager Darrell Bailey.

WANTED—OBSTETRICIAN-GYNECOLOGIST—Seventeen man multi-specialist group, located in the beautiful Hiawatha Valley, 50 miles south of Minneapolis and St. Paul. Seeks Board Certified or eligible OB-GYN to join present two-man department. Full sharing in delivery and major surgery at once. No pregnancy terminations. Send curriculum vitae and brief background sketch, experience, family data, etc. Write: MINNESOTA MEDICINE-488, 375 Jackson St., St. Paul 55101.

GENERAL SURGEON, board qualified or certified, trained in trauma to join two surgeons in suburban Minneapolis. Salary commensurate with experience. Early partnership. Liberal corporate fringe benefits. Write: MINNESOTA MEDICINE-489, 375 Jackson St., St. Paul 55101.

G.P.-SURGEON—Age 48—Considering relocation due to losing associate and excessive practice demands. Presently Chief of Staff, J.C.A.H. Hospital. Excellent references. Extensive experience all phases of general, traumatic and orthopedic surgery including cystoscopy. Prefer small G.P. group, small or rural community, with excellent hospital and clinic facilities and adequate surgical load. All non-metropolitan locations considered. Write: MINNESOTA MEDICINE-490, 375 Jackson, St. Paul 55101.

COLLEGE PHYSICIAN—Part-time College Physician (4/5 time-9 months) for September 19, 1973-June 1, 1974. Interested applicants should forward complete vitae prior to August 15, 1973 to Dr. Harry Brauer, Director, Student Health Service, Mankato State College, Mankato, Minnesota. We welcome the applications of women and minority persons.

GENERAL PRACTITIONER seeking association on a fixed hourly and/or four day week. No call basis. Twenty-six years active practice. Desires location in St. Paul or eastern suburbs. Well known in medical circles. Write: MINNESOTA MEDICINE-487, 375 Jackson St., St. Paul 55101.

Salmonella Typhimurium Gastroenteritis

Statewide Outbreak

D. S. FLEMING, M.D.,* JAN PAPRA,† MARY ANN STOFFELS,‡ and RUSSELL HAVIR‡

DURING APRIL AND MAY 1972, Minnesota reported increased numbers of salmonella typhimurium isolations compared to earlier months in 1972 and similar periods in 1971. Increased isolations were also noted in Wisconsin, Michigan and Illinois. In Minnesota, cases were identified in 20 counties, but the majority were in the metropolitan area with clustering in the lower socioeconomic areas. Typically, the clinical picture was like dysentery. All ages were affected. The majority of reported cases were hospitalized. A preliminary survey of 13 cases failed to identify a common source. In many households multiple cases were observed.

A sample of isolates from Minnesota (10/12) and from Wisconsin (6/6) were found to be Phage Type II and failed to utilize Jordan's tartrate. These common properties suggested a common source and prompted further investigations.

The common source character of the outbreak is evident from the epidemiological curve (Figure). Most cases occurred over the six week period in May and early June. Cases were reported in 20 counties. There were only eight counties which reported two or more cases. Eighty-eight percent of the cases occurred in the Minneapolis-St. Paul area (including the surrounding five counties) and in Olmsted County, an area which comprises 47% of the state's population. The attack rate statewide was 5.6 cases per 100,000 population. The highest attack rate was in Olmsted County, 17.8.

The first Salmonellosis Case Investigation Survey of 46 cases and 36 controls, using epidemiological investigation, failed to identify any food item or other common exposure which was clearly

associated with illness. There were three items on this list which were commonly consumed by both cases and controls and it was not possible to exclude them from consideration since almost everyone who was ill had been exposed. Furthermore these items were general food items and it was possible that some specific brand or type was involved. These items were milk, eggs and hamburger. A large number of other food items were excluded because of the large number of ill persons who had not been exposed making the attack rates between the exposed and not exposed groups insignificantly different.

Hamburger exposure became the focus of a second survey when investigations in Wisconsin identified raw beef as a significant item. In this second survey the probability of illness increased as the amount of hamburger consumed in the home increased. At eight hamburger meals per month this difference became significant when compared to persons eating less. This difference in attack rates was not observed for steak, roast, poultry or for any item eaten at restaurants. Raw

CASES OF SALMONELLA TYPHIMURIUM BY DATE OF REPORT
Minnesota - January - June 1972

Figure

*Director, Disease Prevention and Control, Minnesota Department of Health, Minneapolis, Minnesota.

†Deputy Director, Immunization Program, Minnesota Department of Health, Minneapolis, Minnesota.

‡Program Representative, Immunization Program, Minnesota Department of Health, Minneapolis, Minnesota.

beef eaters were identified and their attack rate was significantly higher than the attack rate for those not eating raw beef. Including those cases excluded because of possible sources other than common exposure increased the significance of the differences between exposed and not exposed attack rates for hamburger and raw beef consumption but did not affect the differences in attack rates for other food items.

A significant number of unreported cases were uncovered. In the 72 case households surveyed for this possibility, 60 unreported cases were discovered and among non household contacts, 24 additional cases were discovered. The unreported household cases were either co-primary cases (32), secondary (2), or had unknown timing. In 16 households there was contact with a case outside of the household within 72 hours of illness.

Symptoms of reported cases were severe with dysentery-like illness, high fever, severe cramps, diarrhea, the most common symptoms. In addition many patients had nausea and vomiting and some had bloody diarrhea. Most of the reported cases had been hospitalized. A few were considered to be extremely toxic and severely dehydrated. No deaths were reported in Minnesota although there were several in Wisconsin. The illnesses of the unreported cases were milder, many with diarrhea alone. It was expected that only the sickest persons would have stool cultures and hence be reported.

Examination of the stores and distributors supplying beef to cases and controls was nonproductive. Twelve stores provided beef to two or more case households. There were some significant differences but it was not possible to trace these differences back through the store's sources of beef. No significant differences could be identified on this level. For the purpose of these calculations a case or control, exposed to multiple stores, was scored as one exposure for each and the exposures for each store were added to the list of each of their distributors. It was learned that there was a great deal of trading off between each of the suppliers and the stores themselves would vary their suppliers depending on market prices and other factors.

Salmonellosis is an important cause of death among baby calves. Over the first six months of

1972 there was a two fold increase in isolates of salmonella typhimurium at the State Veterinary diagnostic laboratory when compared to 1971. In addition a significant increase in isolates of salmonella typhimurium from free flying birds (such as sparrows) has been reported over the past year. Salmonellosis in other animals, used for food, has fallen under tight regulation and is thought to be a diminishing problem in this region. Other than among baby calves, state veterinarians have not recognized any recent outbreaks of salmonellosis among livestock.

Discussion and Summary

A common source outbreak of salmonella typhimurium has been described epidemiologically. Two hundred and twenty laboratory confirmed cases occurred in Minnesota over the first six months of 1972. Hamburger and raw beef consumption was clearly associated with illness, epidemiologically, but this association was not confirmed with isolations of this organism from beef. Two factors significantly interfered with this investigation: the abrupt termination of the epidemic during the first week of June, at the time the investigation was getting under way, and the long delay interposed between illness and investigation. The former prevented product surveillance and the latter blocked the collection of left over food and muddled the data with failing memories.

Beef distribution is a maze and we were not able to trace cases back through this maze to packing houses where the problem probably originated. The salmonella typhimurium isolated from baby calves were uniformly tartrate positive and hence unrelated to the outbreak in humans. No other epizootics among animals were recognized. It appeared more likely that a breakdown in handling of beef was responsible for this outbreak rather than an epizootic, but this breakdown was not identified.

This outbreak emphasized the potential for widespread outbreaks of food borne illness to occur as the result of contaminated commercial products and, like others, to elude definitive explanation. It is likely that multiple factors play a role in bacteria reaching the consumer (in sufficient numbers to cause illness). Original contamination plus time and temperature all have a role and do not stay together for long.

Staphylococcal Pyomyositis

JAMES D. FETT, M.D., M.P.H.*

ONE OF THE MOST interesting features of bacterial pyomyositis, a common staphylococcal infection reported from many tropical areas,¹⁻⁶ is the remarkable infrequency of the disease in temperate climates although the latter has been reported.⁷⁻⁹ The following study is presented to supplement recent American literature^{8,9} in relation to this subject and to further acquaint physicians with this entity.

Case Report

Twenty-two cases of pyomyositis presented to the Vanga Evangelical Hospital, Vanga, Zaire (formerly Congo), Africa, during the one-year period from March 1971 to February 1972, represented just under one percent of all admissions to the surgical and medical pavillons.

All patients were Bantus. There were 13 males and nine females. Age range was four to 60 with a mean age of 30. Only one patient was a child. In only one case was a definite history of trauma elicitable. No seasonal incidence could be detected. Clinical presentation is indicated in the Table. Distribution of the involved muscles is indicated in the Figure. There were two deaths.

Limited laboratory evaluation revealed leucocytosis up to 21,400 WBC/mm³ in 11 of 17 patients (64.1%). In 13 cases Gram smears obtained of aspirated pus were positive in all cases for Gram positive cocci. Cultures

were obtained in only eight cases† and all grew out coagulase positive *Staphylococcus aureus*.

Hospitalization ranged from five to 34 days with a mean duration of 13.5 days. Routine management included aspiration of suspected areas for pus followed by incision if the aspiration was positive. Aspiration was positive for pus in 17 of 19 cases. In all but one of these subsequent incision resulted in drainage of pus, the quantity varying from a few ccs to over 1 liter. Resolution without drainage occurred in three cases.

Routine antibiotic treatment consisted of 1,200,000 units of Procaine Penicillin G daily in two dosages. Chloramphenicol was used additionally in two cases with prolonged course of illness and methicillin was used in one case. Incidence of penicillin-resistant staphylococci was not known and the use of beta-lactamase-resistant penicillin was very limited because of availability and economic factors.

Discussion

In the overwhelming preponderance of cases of tropical pyomyositis when cultures have been done *Staphylococcus aureus* is found.^{2,4,5,10} Only rarely have other organisms been cultured.^{5,10,13}

TABLE
Symptoms and Signs in 22 Cases of Pyomyositis

	Number of cases
Pain	22 (100%)
Tenderness to palpation	22 (100%)
Fever	21 (95.5%)
Localized swelling	21 (95.5%)
Localized heat	13 (59%)
Fluctuance	5 (23%)
Solitary lesion	13 (59%)
Multiple lesions	9 (41%)
2 abscesses	5
3 abscesses	4

*Vanga Evangelical Hospital, Vanga, Republic of Zaire, Africa, and University of Minnesota Unit in Internal Medicine, Northwestern Hospital, Minneapolis, Minnesota.

Reprint requests should be addressed to: Dr. James Fett, 221 So. Madison, Pierre, South Dakota 57501.

†We were able to develop culture facilities in our rural hospital only after the beginning of the study.

Figure—Distribution of lesions.

In Staphylococcal pyomyositis the accumulation of pus is always intramuscular within the confines of the deep fascia. Pus, varying from a few ccs to over a liter, is creamy greenish-yellow. We did not find the reddish-purple pus as described by Robin,⁵ possibly because our patients presented earlier.

Numerous predisposing causes have been suggested, including Vitamin C deficiency, sickle cell anemia, multiple small trauma, malnutrition, parasitoses including filariasis, ankylostomiasis, malaria, ascariasis; but none of these has been demonstrated conclusively to be related.^{1,3-6,10}

Tropical climatic conditions seem to play an important role in view of the relative rarity of the disease in temperate climates and the absence of the disease in tropical areas at high altitude only short distances removed from low-altitude regions where the disease is common.^{1,3,4,6}

The clinical triad of pain with movement, fever, and localized swelling, appearing in that order, is the usual finding. Contrary to the report of Levin et al.⁸ we have found pain to be a very prominent feature even from early in the course of the disease. Induration occurs later and fluctuation only very late.

Any large muscle group may be involved. The most common site is the thigh. When there are multiple sites they are usually in different stages of progression indicating that there is probably a primary site with other sites being secondary; however, multiple simultaneous-evolving sites are observed. The origin of the Staphylococci cannot usually be determined,^{3,5} although minor super-

ficial infection is suspected.^{4,6}

Differential diagnosis includes: osteomyelitis, sickle-cell crisis, septic arthritis, thrombophlebitis, trauma with hematoma formation, malaria, and cellulitis.

Typically, pain, fever, and swelling become more intense until the abscess is drained. In some instances, particularly in the case of secondary lesions, when antibiotic treatment is instituted early resolution may occur without incision.^{5,6} Persistent fever and pain indicate encapsulated pus and the need for drainage. Drainage results in rapid improvement.

Ideal management includes adequate drainage, culture of pus with antibiotic sensitivity analysis, and appropriate antibiotic therapy. Because of the frequency of penicillin-resistant staphylococci the use of a betalactamase-resistant penicillin is desirable, though the unavailability and high cost constitute practical problems in many medical facilities in developing countries. The importance of adequate drainage is underlined, rapid healing being as much or more related to adequate drainage as to antibiotic treatment.

Mortality should be very low. In the present series mortality was attributed to improper drainage by a village "medicinemán" in one case with complicating gas gangrene and septicemia and in the other case an anaphylactic reaction to penicillin appears to have been responsible. Metastatic infection to non-muscular tissue did not occur in this series and is reported to be extremely uncommon.^{3,4} Healing is without apparent residual.

Minnesota Dermatological Society

Minnesota Dermatological Society, Quarterly Clinical Meeting, September 8-9, Mayo Clinic, Rochester. Program Chairman: Bruce Bart, M.D.

Legislation

Medicine, the Legislature, and You

THE 68TH MINNESOTA LEGISLATURE is now in recess after expending slightly more than half of its allotted 120 days in session. Between the first Monday in January and the 21st day of May, 201 Minnesota legislators introduced more than 5000 (including companion) bills into the Senate and the House of Representatives.

From this profusion of legislation at least 400 bills were reviewed by MSMA which dealt directly or indirectly with health or medical care. Details regarding the specific bills introduced, considered and enacted have been reported in the Minnesota State Medical Association's (MSMA) Newspaper. Only 60 of these 400 plus health related measures were signed into law during this legislative session leaving over 300 either in committee or at some other stage in the legislative process. Under the new flexible session rule provided for by the constitutional amendment passed last fall the legislature will officially reconvene on January 15, 1974 to act on these as well as other bills which will be introduced. During the interim various standing committees and their subcommittees will meet during one week of each month to hear testimony and make recommendations on many of these proposals which could be enacted into law in 1974. In addition committees will be considering new legislation which will be introduced unofficially before the session reconvenes. The advent of the flexible session rule has considerably increased the legislative workload of MSMA, which, coupled with the growing focus on health care at all levels of government, makes legislative affairs a major responsibility of the State Medical Association.

A discussion of the Association's role in the legislative process therefore seems pertinent, and to adequately meet this growing legislative challenge to medicine it is vital for more physicians to make themselves knowledgeable, interested and involved in the legislative process as it affects medicine and public health.

MSMA's legislative modus operandi is designed to permit and encourage extensive physician participation at the grass roots level. Success (or failure) of the legislative program rests to a large degree on how well individual physicians have functioned as cogs of the MSMA legislative wheel.

While the Association policy is set by the

House of Delegates and/or the Council, the Committee on Public Policy is charged with the final responsibility for implementation of the Association's legislative policy dictates. This committee is comprised of a chairman, a vice chairman and one representative from each of the nine Councilor districts. In addition there exists a Liaison Public Policy Committee of 67 members each representing one of the 67 Minnesota State Senate Districts, whose primary responsibility is to function as local contact persons for the senators and representatives in each district or to see that other physicians are enlisted for this responsibility.

MSMA's Legislative Representative and/or Legal Counsel are at the Capitol daily during the session making personal contacts and monitoring the steady flow of bills. It is virtually impossible though for them to keep in continued contact with all 201 senators and representatives on each medical issue of importance, so it is essential that there be dependable contact persons assigned to each legislator to augment MSMA staff efforts at the Capitol. Contacts are usually physicians, but in some cases doctor's wives or clinic managers also function in this capacity.

Legislative bulletins and special letters are sent to legislative contact persons at regular intervals during each session stressing communication with each legislator on those issues deemed important to medicine at that time. Special emphasis is obviously placed on contacting members of the various committees which are considering particular bills before they reach the Senate or House floor. Additional contact physicians or physicians' wives can always be utilized. Those interested in assisting the Association's legislative effort with particular legislators should contact the State Office or a member of the Public Policy Committee so they can be added to the Association's list for legislative mailings.

Every physician, whether or not an officially designated legislative contact, is urged to make it his or her responsibility to become acquainted with his senator and representative. More than ever, legislators are in need of medical input on legislation, particularly from their physician constituents. All too often legislators tell our lobbyist that they have little or no contact with the medical profession in their home district. As a

result they often lack guidance in voting on important medical issues.

Physicians may communicate with their legislators by letter, telegram or phone call but the best means of influencing legislative opinion is by a personal visit. While it is sometimes difficult to arrange a personal visit with a legislator during the session there is generally ample opportunity to do so during the interim. Such a visit may be a social affair, with or without spouse, formal or informal, breakfast, lunch, or dinner. Regardless of the format it can be an interesting, productive and rewarding experience.

Approximately one-third of this legislature are first termers who are hungry for information from professionals or interest groups in fields where they have little background or knowledge. The only physician serving in this legislature is Dr. John Salchert, a Minneapolis family physician, who is highly respected by his fellow legislators and continually sought after for advice on medical legislation. It would be extremely desirable for medicine to have more physician legislators like Dr. Salchert, however, any doctor can help influence legislative opinion by communicating personally with his or her representatives in St. Paul from time to time. Legislators respect numbers, and the more contact they have with more doctors, the better they listen.

Some county medical societies regularly invite legislators to special society legislative meetings each year, a practice which every society should include as a regular part of their society activities. Most state legislators are anxious to receive public exposure, and they are quite willing to meet with medical groups especially during election years.

Physician involvement in the legislative process must include testimony before Senate and House committees on specific medically related proposals. Frequently the nature of pending legislation is such as to require testimony from physicians

with special expertise in certain areas of medical practice. Because hearings are often scheduled on very short notice it is sometimes difficult for the Association's lobbyist to obtain appropriate testimony. Physicians who are knowledgeable and can present a comprehensive statement of pertinent facts to legislative committees in specific areas of legislative concern are encouraged to make themselves available to speak on behalf of the Association when committee testimony is required.

Most important is the need for more physician involvement in the political arena. The precursor of sound health legislation is without question a receptive and favorable climate for Association representatives to present their views. No longer should politics be considered beneath the professional dignity of the physician. Medical decisions are being made by politicians and unless physicians assist and participate in electing responsible representatives the efforts of the Public Policy Committee will bear little fruit. Though more could be written on this subject suffice it to say that the best individual physician lobbying can be done at campaign time—when the legislative candidate needs assistance. The value of a physician's support for a candidate can not be too highly stressed. Elected officials are understandably very receptive to those who stood up to be counted during the heat of a campaign.

MINNPAC has been encouraging such physician involvement in both political parties for over 10 years in Minnesota, but the membership dollars of more physicians are needed if medicine is to increase its political impact. Although the final analysis reveals many ingredients of successful medical legislative effort, campaign involvement heads the list. It is a truism that the battles fought on Capitol Hill are usually won on the campaign trails.

Neurosurgical Problems Related to Trauma

The Department of Neurosurgery and the Office of Postgraduate Medical Education of the University of Minnesota course in "Neurosurgical Problems to Trauma" to be held at the Nolte Center for Continuing Education on the Minneapolis Campus, September 7-8, 1973. Program has been planned jointly with the Minnesota Academy of Family Physicians.

This course is designed primarily for family physicians, pediatricians and internists.

Fee: \$80.00.

Further information may be obtained from the Office of Postgraduate Medical Education, University of Minnesota, Room 205, Nolte Center for Continuing Education, Minneapolis, Minnesota 55455, or by calling (612) 373-8012.

"Lighthouse"

Tague C. Chisholm, M.D.

SEPTEMBER, 1973

Everybody experiences psychic tension.

Most people can handle this tension.

Some people develop excessive psychic tension and need your counseling,

and a few may need counseling
and the psychotropic action of Valium® (diazepam).

Before deciding to make Valium (diazepam) part of your treatment plan, check on whether or not the patient is presently taking drugs, if so, what his response has been. Along with the medical and family history, this information can help you determine initial dosage, possibility of side effects and ultimate prospects of success or failure.

While Valium can be a most useful adjunct to your counseling, it should be prescribed only as long as excessive psychic tension persists and should be discontinued when you decide it has accomplished its therapeutic task. In general, when dosage guidelines are followed, Valium is well tolerated (see Dosage). For convenience it is available in 2-mg, 5-mg and 10-mg tablets.

Drowsiness, fatigue and ataxia have been the most commonly reported side effects.

Until response is determined, patients receiving Valium should be cautioned against engaging in hazardous occupations requiring complete mental alertness, such as driving or operating machinery.

Before prescribing, please consult complete product information, a summary of which follows:

Indications: Tension and anxiety states; somatic complaints which are concomitants of emotional factors; psychoneurotic states manifested by tension, anxiety, apprehension, fatigue, depressive symptoms or agitation; symptomatic relief of acute agitation, tremor, delirium tremens and hallucinosis due to acute alcohol withdrawal; adjunctively in skeletal muscle spasm due to reflex spasm to local pathology, spasticity caused by upper motor neuron disorders, athetosis, stiff-man syndrome, convulsive disorders (not for sole therapy).

Contraindicated: Known hypersensitivity to the drug. Children under 6 months of age. Acute narrow angle glaucoma; may be used in patients with open angle glaucoma who are receiving appropriate therapy.

Warnings: Not of value in psychotic patients. Caution against hazardous occupations requiring complete mental alertness. When used adjunctively in convulsive disorders, possibility of increase in frequency and/or severity of grand mal seizures may require increased dosage of standard anticonvulsant medication; abrupt withdrawal may be associated with temporary increase in frequency and/or severity of seizures. Advise against simultaneous ingestion of alcohol and other CNS depressants. Withdrawal symptoms (similar to those with barbiturates and alcohol) have occurred following abrupt discontinuance (convulsions, tremor, abdominal and muscle cramps, vomiting and sweating). Keep addiction-prone individuals under careful surveillance because of their predisposition to habituation and dependence. In pregnancy, lactation or women of childbearing age, weigh potential benefit against possible hazard.

Precautions: If combined with other psychotropics or anticonvulsants, consider carefully pharmacology of agents employed; drugs such as phenothiazines, narcotics, barbiturates, MAO inhibitors and other antidepressants may potentiate its action. Usual precautions indicated in patients severely depressed, or with latent depression, or with suicidal tendencies. Observe usual precautions in impaired renal or hepatic function. Limit dosage to smallest effective amount in elderly and debilitated to preclude ataxia or oversedation.

Side Effects: Drowsiness, confusion, diplopia, hypotension, changes in libido, nausea, fatigue, depression, dysarthria, jaundice, skin rash, ataxia, constipation, headache, incontinence, changes in salivation, slurred speech, tremor, vertigo, urinary retention, blurred vision. Paradoxical reactions such as acute hyperexcited states, anxiety, hallucinations, increased muscle spasticity, insomnia, rage, sleep disturbances, stimulation have been reported; should these occur, discontinue drug. Isolated reports of neutropenia, jaundice; periodic blood counts and liver function tests advisable during long-term therapy.

Dosage: Individualize for maximum beneficial effect.

Adults: Tension, anxiety and psychoneurotic states, 2 to 10 mg b.i.d. to q.i.d.; alcoholism, 10 mg t.i.d. or q.i.d. in first 24 hours, then 5 mg t.i.d. or q.i.d. as needed; adjunctively in skeletal muscle spasm, 2 to 10 mg t.i.d. or q.i.d.; adjunctively in convulsive disorders, 2 to 10 mg b.i.d. to q.i.d. *Geriatric or debilitated patients:* 2 to 2½ mg, 1 or 2 times daily initially, increasing as needed and tolerated. (See Precautions.) *Children:* 1 to 2½ mg t.i.d. or q.i.d. initially, increasing as needed and tolerated (not for use under 6 months).

Supplied: Valium® (diazepam) Tablets, 2 mg, 5 mg and 10 mg; bottles of 100 and 500. All strengths also available in Tel-E-Dose® packages of 1000.

DIRECTOR
of
MENTAL HEALTH

We are seeking a psychiatrist to direct the Milwaukee County Mental Health Center, a comprehensive community mental health center, organized into six catchment area programs including outreach stations located within the community. 1,000 acute and long-term psychiatric beds; an ultra modern day hospital; and, a soon to be completed 180 bed inpatient resident and day care treatment center for children and adolescents. The Center is a principal psychiatric teaching resource for the Medical College of Wisconsin and has training programs for interns, residents, nurses and other students.

Requires Wisconsin licensure or eligibility for same and at least 5 years comprehensive experience as a mental health director, educator, or administrator preferably in an accredited mental health program, university or hospital.

This is a timely opportunity since we can offer the person appointed to this position the chance to make several critical appointments to new subordinate positions. Excellent employee fringe benefit program and salary. Send vita to:

Edwin A. Mundy, Director
Institutions & Departments
8731 Watertown Plank Rd.

Bobo's back at the big top

After a rheumatoid arthritic flare-up.

Vote. This drug is not a simple analgesic. Do not use casually. Carefully evaluate patients before treatment and keep them under close supervision. Obtain a detailed history, and complete laboratory examination (complete hematology, etc.) before prescribing and at frequent intervals thereafter. Carefully select patients, those responsive to routine measures, contraindicated patients or those who cannot be observed frequently. Warn patients not to exceed recommended short-term relief of severe symptoms with the possible dosage is the goal of therapy. Dosage should be taken with meals or a full glass of milk. Subcapsules for tablets if dyspeptic symptoms. Patients should discontinue the drug and report any sign of: fever, sore throat, oral lesions (of blood dyscrasia), dyspepsia, epigastric pain, black or tarry stools or other signs of intestinal ulceration or hemorrhage, skin rash, significant weight gain or edema. A one-week trial is adequate. Discontinue in the absence of a response. Restrict treatment periods to one week in patients over sixty.

Acute gouty arthritis, rheumatoid arthritis, spondylitis.

Contraindications: Children 14 years or less; senile psychosis or symptoms of G.I. inflammation or ulceration; severe, recurrent or persistent dyspepsia or presence of drug allergy; blood dyscrasia; renal, hepatic or cardiac dysfunction; hypothyroidism; systemic edema, and salivary gland enlargement due to the disease. Nephritic and temporal arteritis; patients receiving other potent chemotherapeutic agents; long-term anticoagulant therapy.

Age, weight, dosage, duration of therapy, excretion, concomitant diseases, and concurrent potent drugs may affect incidence of toxic reactions. Carefully select and observe the individual patient, especially in (forty years and over) who have increased susceptibility to the toxicity of the drug. Use with caution in first trimester of pregnancy.

Butazolidin® alka Geigy

Each capsule contains:
100 mg. phenylbutazone USP
100 mg. dried aluminum hydroxide gel USP
150 mg. magnesium trisilicate USP

If it doesn't work in a week, forget it.

and in nursing mothers. Drug may appear in cord blood and breast milk. Serious, even fatal, blood dyscrasias, including aplastic anemia, may occur suddenly despite regular hemograms, and may become manifest days or weeks after cessation of drug. Any significant change in total white count, relative decrease in granulocytes, appearance of immature forms, or fall in hematocrit should signal immediate cessation of therapy and complete hematologic investigation. Unexplained bleeding involving CNS, adrenals, and G.I. tract has occurred. The drug may potentiate action of insulin, sulfonylurea, and sulfonamide-type agents. Carefully observe patients taking these agents. Nontoxic and toxic goiters and myxedema have been reported (the drug reduces iodine uptake by the thyroid). Blurred vision can be a significant toxic symptom worthy of a complete ophthalmological examination. Swelling of ankles or face in patients under sixty may be prevented by reducing dosage. If edema occurs in patients over sixty, discontinue drug.

Precautions: The following should be accomplished at regular intervals. Careful detailed history for disease being treated and detection of earliest signs of adverse reactions, complete physical examination including check of patient's weight, complete weekly (especially for the aging) or an every two week blood check, pertinent laboratory studies. Caution patients about participating in activity requiring alertness and coordination, as driving a car, etc. Cases of leukemia have been reported in patients with a history of short- and long-term therapy. The majority of these patients were over forty. Remember that arthritic-type pains can be the presenting symptom of leukemia.

Adverse Reactions: This is a potent drug; its misuse can lead to serious results. Review detailed information before beginning therapy. Ulcerative esophagitis, acute

and reactivated gastric and duodenal ulcer with perforation and hemorrhage, ulceration and perforation of large bowel, occult G.I. bleeding with anemia, gastritis, epigastric pain, hematemesis, dyspepsia, nausea, vomiting and diarrhea, abdominal distention, agranulocytosis, aplastic anemia, hemolytic anemia, anemia due to blood loss including occult G.I. bleeding, thrombocytopenia, pancytopenia, leukopenia, leukopenia, bone marrow depression, sodium and chloride retention, water retention and edema, plasma dilution, respiratory alkalosis, metabolic acidosis, fatal and nonfatal hepatitis (cholestasis may or may not be prominent), petechiae, purpura without thrombocytopenia, toxic pruritus, erythema nodosum, erythema multiforme, Stevens-Johnson syndrome, Lyell's syndrome (toxic necrotizing epidermolysis), exfoliative dermatitis, serum sickness, hypersensitivity angitis (polyarteritis), anaphylactic shock, urticaria, arthralgia, fever, rashes (all allergic reactions require prompt and permanent withdrawal of the drug), proteinuria, hematuria, oliguria, anuria, renal failure with azotemia, glomerulonephritis, acute tubular necrosis, nephrotic syndrome, bilateral renal cortical necrosis, renal stones, ureteral obstruction with uric acid crystals due to uricosuric action of drug, impaired renal function, cardiac decompensation, hypertension, pericarditis, diffuse interstitial myocarditis with muscle necrosis, perivascular granuloma, aggravation of temporal arteritis in patients with polymyalgia rheumatica, optic neuritis, blurred vision, retinal hemorrhage, toxic amblyopia, retinal detachment, hearing loss, hyperglycemia, thyroid hyperplasia, toxic goiter, association of hyperthyroidism and hypothyroidism (causal relationship not established), agitation, confusional states, lethargy, CNS reactions associated with overdosage, including convulsions, euphoria, psychosis, depression, headaches, hallucinations, giddiness, vertigo, coma, hyperventilation, insomnia, ulcerative stomatitis, salivary gland enlargement. More than sleep

your choice of sleep medication
is wisely based on more than
sleep-inducing potential

sleep with relative safety

Chronic tolerance studies have confirmed the relative safety of Dalmane (flurazepam HCl); no depression of cardiac or respiratory function was noted in patients administered recommended or high doses for as long as 90 consecutive nights.

In most instances when adverse reactions were reported, they were mild, infrequent and self-resolving, requiring discontinuance of therapy. Morning "hang-over" with Dalmane has been relatively infrequent. Drowsiness, lightheadedness and the like have been the side effects noted most frequently, particularly in the elderly and debilitated. (An initial dose of Dalmane 15 mg should be prescribed for these patients.)

sleep for 7 to 8 hours
without need to
repeat dosage

No sleep studies have been as rigorously evaluated in the sleep research laboratory as Dalmane. Insomnia patients given one 30-mg capsule of Dalmane at bedtime, on average: fell asleep within 17 minutes, had fewer awakenings, spent less time awake after sleep onset, and slept for 7 to 8 hours with no need to repeat dosage during the night.

ep with
sistency

Dalmane (flurazepam HCl) is a distinctive sleep medication—a benzodiazepine specifically indicated for insomnia. It is not a barbiturate or methaqualone, nor is it related chemically to any other hypnotic.

When your evaluation of insomnia indicates the need for a sleep medication, consider Dalmane—a single entity nonnarcotic, non-habit-forming agent proved effective and relatively safe for relief of insomnia.

Dalmane has been shown to be consistently effective even during consecutive nights of administration, with no need to increase dosage.

DALMANE[®]
(flurazepam HCl)

**When restful sleep
is indicated**

One 30-mg capsule h.s. —usual adult dosage
(15 mg may suffice in some patients).

One 15-mg capsule h.s. —initial dosage for elderly or debilitated patients.

Before prescribing Dalmane (flurazepam HCl), please consult Complete Product Information, a summary of which follows:

Indications: Effective in all types of insomnia characterized by difficulty in falling asleep, frequent nocturnal awakenings and/or early morning awakening in patients with recurring insomnia or poor sleeping habits, and in acute or chronic medical situations requiring restful sleep. Since insomnia is often transient and intermittent, prolonged administration is generally not necessary or recommended.

Contraindications: Known hypersensitivity to flurazepam HCl.

Warnings: Caution patients about possible combined effects with alcohol and other CNS depressants. Caution against hazardous occupations requiring complete mental alertness (e.g., operating machinery, driving). Use in women who are or may become pregnant only when potential benefits have been weighed against possible hazards. Not recommended for use in persons under 15 years of age. Though physical and psychological dependence have not been reported on recommended doses, use caution in administering to addiction-prone individuals or those who might increase dosage.

Precautions: In elderly and debilitated, initial dosage should be limited to 15 mg to preclude oversedation, dizziness and/or ataxia. If combined with other drugs having hypnotic or CNS-depressant effects, consider potential additive effects. Employ usual precautions in patients who are severely depressed, or with latent depression or suicidal tendencies. Periodic blood counts and liver and kidney function tests are advised during repeated therapy. Observe usual precautions in presence of impaired renal or hepatic function.

Adverse Reactions: Dizziness, drowsiness, lightheadedness, staggering, ataxia and falling have occurred, particularly in elderly or debilitated patients. Severe sedation, lethargy, disorientation and coma, probably indicative of drug intolerance or overdosage, have been reported. Also reported were headache, heartburn, upset stomach, nausea, vomiting, diarrhea, constipation, GI pain, nervousness, talkativeness, apprehension, irritability, weakness, palpitations, chest pains, body and joint pains and GU complaints. There have also been rare occurrences of sweating, flushes, difficulty in focusing, blurred vision, burning eyes, faintness, hypotension, shortness of breath, pruritus, skin rash, dry mouth, bitter taste, excessive salivation, anorexia, euphoria, depression, slurred speech, confusion, restlessness, hallucinations, and elevated SGOT, SGPT, total and direct bilirubins and alkaline phosphatase. Paradoxical reactions, e.g., excitement, stimulation and hyperactivity, have also been reported in rare instances.

Dosage: Individualize for maximum beneficial effect. *Adults:* 30 mg usual dosage. 15 mg may suffice in some patients. *Elderly or debilitated patients:* 15 mg initially until response is determined.

Supplied: Capsules containing 15 mg or 30 mg flurazepam HCl.

A topical steroid that has clinically succeeded

*in study...after study...after study*¹⁻⁶

Excellent/good results

85% in psoriasis
(150 of 177 patients)¹

92% in atopic eczema
(231 of 251 patients)¹

Schering

Valisone[®]

brand of

betamethasone valerate (0.1%) Cream/Ointment

Plus economy B.i.d. dosage often found effective!
Available in 5, 15, and 45 Gm. tubes.

6% in contact dermatitis
(81 of 84 patients)¹

CLINICAL CONSIDERATIONS:

Description VALISONE products contain betamethasone valerate (9-fluoro-11 β ,17,21-trihydroxy-16 β -methylpregna-1,4-diene-3,20-dione 17-valerate). Each gram of VALISONE Cream 0.1% contains 1.2 mg. betamethasone valerate (equivalent to 1.0 mg. betamethasone) in a soft, white, hydrophilic cream of water, mineral oil, petrolatum, polyethylene glycol 1000 monooctyl ether, cetostearyl alcohol, monobasic sodium phosphate, and phosphoric acid; 4-chloro-m-cresol is present as a preservative. Each gram of VALISONE Ointment 0.1% contains 1.2 mg. betamethasone valerate (equivalent to 1.0 mg. betamethasone) in an ointment base of liquid and white petrolatum, and hydrogenated lanolin. VALISONE Cream and Ointment contain no parabens.

Indications VALISONE Cream and Ointment are indicated for the relief of the inflammatory manifestations of corticosteroid-responsive dermatoses.

Contraindications VALISONE Cream and Ointment are contraindicated in vaccinia and varicella. Topical steroids are contraindicated in those patients with a history of hypersensitivity to any of the components of the preparation.

Precautions If irritation develops with the use of VALISONE Cream or Ointment, treatment should be discontinued and appropriate therapy instituted. In the presence of an infection, the use of an appropriate antifungal or antibacterial agent should be instituted. If a favorable response does not occur promptly, the corticosteroid should be discontinued until the infection has been adequately controlled. If extensive areas are treated or if the occlusive technique is used, the possibility exists of increased systemic absorption of the corticosteroid and suitable precautions should be taken. Although topical steroids have not been reported to have an adverse effect on pregnancy, the safety of their use in pregnant females has not been absolutely established. Therefore, they should not be used extensively in pregnant patients, in large amounts, or for prolonged periods of time. VALISONE Cream and Ointment are not for ophthalmic use.

Adverse Reactions The following local adverse reactions have been reported with topical corticosteroids: burning, itching, irritation, dryness, folliculitis, hypertrichosis, acneiform eruptions, and hypopigmentation. The following may occur more frequently with occlusive dressings than without such therapy: maceration of the skin, secondary infection, skin atrophy, striae, and miliaria.

Dosage and Administration Apply a thin film of VALISONE Cream or Ointment to the affected skin areas one to three times a day. Clinical studies of VALISONE have indicated that dosage only once or twice a day is often feasible and effective. AUGUST 1972
For more complete details, consult Schering literature available from your Schering Representative or Professional Services Department, Schering Corporation, Kenilworth, New Jersey 07033.

ROCHE announces
new

BACTRIMTM

Each tablet contains 80 mg trimethoprim and 400 mg sulfamethoxazole.

a new type of antibacterial for a two-pronged attack against chronic urinary tract infections due to susceptible organisms

Bactrim is highly effective in the treatment of these infections – primarily pyelonephritis, pyelitis and cystitis, when due to susceptible organisms (usually *E. coli*, *Klebsiella-Enterobacter*, *Proteus mirabilis*, and, less frequently, indole-positive proteus species). This efficacy is related to the unique mode of action against bacteria (see opposite page), an action that, in effect, makes Bactrim a new type of antibacterial.

Bactrim significantly superior to constituents in patients with obstructive complications

In the presence of obstructive uropathy, Bactrim has demonstrated efficacy which is superior to either sulfamethoxazole or trimethoprim alone against susceptible organisms. In addition, *in vitro** studies have shown that bacterial resistance develops more slowly with Bactrim than with either trimethoprim or sulfamethoxazole alone.

*Please note that clinical conclusions cannot be extrapolated from *in vitro* studies.

Interrupts life cycle of susceptible bacteria

The mode of action interrupts the life cycle at two important points, thereby impeding the production of nucleic acids and proteins essential to these bacteria. These consecutive interruptions occur because sulfamethoxazole and trimethoprim resemble naturally existing substrates. By competitive replacement of these substrates, they inhibit further synthesis.

new **BACTRIM**TM

Each tablet contains 80 mg trimethoprim and 400 mg sulfamethoxazole.

for chronic urinary tract infections

Before prescribing, please see complete product information on last page of advertisement.

Excellent clinical response in chronic urinary tract infections

A multiclinic, double-blind study* of response to a ten-day course of therapy in 471† patients with chronic urinary tract infections demonstrated the superiority of Bactrim. On the 10th day after initiation of therapy, 91.7% (of 168 patients) showed significant bacteriological response to Bactrim compared with 81.2% (of 144 patients) to trimethoprim and 64.5% (of 155 patients) to sulfamethoxazole. In patients with obstructive complications, 10th day response was 94.8% (of 97 patients) to Bactrim, 72.9% (of 85 patients) to trimethoprim and 58.5% (of 94 patients) to sulfamethoxazole.

Excellent response maintained

Bactrim proved equally impressive in maintaining this bacteriological response. In the above study, after ten-day therapy with Bactrim, 68.4% of patients with chronic urinary tract infections maintained response for up to 42 consecutive days, compared with 59.7% with trimethoprim and 44.4% with sulfamethoxazole. In patients with obstruction, 70.8% of those on Bactrim maintained response for up to 42 consecutive days, compared

with 49.4% on trimethoprim and 38.8% on sulfamethoxazole. The figures are particularly remarkable in cases with urinary obstruction—cases regarded as being notoriously difficult to treat.

To date, low incidence of significant side effects

Although Bactrim demonstrated impressive results, it is important to note that the incidence of clinically significant adverse effects was low, including nausea and/or vomiting, rash, leukopenia, SGPT increase and creatinine increase.

Bactrim should be given with caution to patients with impaired renal or hepatic function, possible folate deficiency and to those with severe allergic bronchial asthma. Adequate fluid intake must be maintained. Complete blood counts, urinalysis, careful microscopic examination, and renal function tests should be performed during therapy.

Currently, the increasing frequency of resistant organisms is a limitation of the usefulness of all antibacterial agents, especially in the treatment of chronic and recurrent urinary tract infections.

Usual adult dosage: two tablets every twelve hours for 10 to 14 days; no loading dose required.

* Data on file, Hoffmann-La Roche Inc., Nutley, N.J. 07110.
† 4 patients not available for evaluation at day 10.

new **BACTRIM**TM

Each tablet contains 80 mg trimethoprim and 400 mg sulfamethoxazole.

for chronic urinary tract infections

Roche Laboratories
Division of Hoffmann-La Roche Inc.
Nutley, N.J. 07110

Before prescribing, please consult complete product information on facing page.

Product Information:

Indication: Bactrim is a synthetic antibacterial combination product consisting of two active ingredients: trimethoprim and sulfamethoxazole. Each tablet contains 80 mg trimethoprim and 400 mg sulfamethoxazole.

Chemical Structure: Trimethoprim is 2,4-diamino-5-(3,4,5-trimethoxybenzyl) pyrimidine. Sulfamethoxazole is a white to light-yellow, odorless, bitter compound with a molecular weight of 290.3.

Pharmacology: Sulfamethoxazole is *N*-(5-methyl-3-isoxazolyl)sulfanilamide. It is a white to light-yellow, odorless, tasteless compound with a molecular weight of 253.28.

Microbiology: Sulfamethoxazole inhibits bacterial synthesis of folic acid by competing with para-aminobenzoic acid. Trimethoprim blocks the production of tetrahydrofolic acid from dihydrofolic acid by binding to and reversibly inhibiting the required dihydrofolate reductase. Thus, Bactrim blocks two consecutive steps in the biosynthesis of nucleic acids and proteins in many bacteria.

Resistance: Studies have shown that bacterial resistance develops more rapidly with Bactrim than with trimethoprim or sulfamethoxazole alone.

Sensitivity: Serial dilution tests have shown that the spectrum of antibacterial activity of Bactrim includes the common urinary tract pathogens with the exception of *Pseudomonas aeruginosa*. The following organisms are usually susceptible: *Escherichia coli*, *Klebsiella aerobacter*, *Proteus mirabilis* and indole-positive proteus.

Representative Minimum Inhibitory Concentration Values for Bactrim-Susceptible Organisms (MIC—mcg/ml)

	Trimethoprim alone	Sulfamethoxazole alone	TMP/SMX (1:20)	
			TMP	SMX
<i>Shigella</i>	0.05—1.5	1.0 —245	0.05—0.5	0.95— 9.5
<i>S. dysenteriae</i> (Sdp. positive)	0.5 —5.0	7.35 —300	0.05—1.5	0.95—28.5
<i>Shigella flexneri</i>	0.5 —1.5	7.35 — 30	0.05—0.15	0.95— 2.85
<i>Shigella sonnei</i>	0.15—5.0	0.735—245	0.05—1.5	0.95—28.5

Pharmacokinetics: Bactrim is rapidly absorbed following oral administration. The blood levels of trimethoprim and sulfamethoxazole are similar to those achieved when each component is given alone. Peak blood levels for the individual components occur one hour after oral administration. The half-lives of sulfamethoxazole and trimethoprim, 10 and 16 hours respectively, are relatively constant regardless of whether these compounds are administered as individual components or as Bactrim. Detectable levels of trimethoprim and sulfamethoxazole are present in the blood 2 hours after drug administration. Free sulfamethoxazole and trimethoprim blood levels are proportionately dose-dependent. Following administration, the steady-state ratio of trimethoprim to sulfamethoxazole levels in the blood is about 1:20.

Metabolism: Sulfamethoxazole exists in the blood as free, conjugated and protein-bound forms; trimethoprim is present as free, protein-bound and metabolized forms. The free forms are considered to be the pharmacologically active forms. Approximately 44 percent of trimethoprim and 70 percent of sulfamethoxazole are protein-bound in the blood. The presence of 10 mg percent sulfamethoxazole in plasma does not influence the protein binding of trimethoprim. The protein binding of trimethoprim does not influence the protein binding of sulfamethoxazole.

Excretion: Bactrim is chiefly excreted by the kidneys through both glomerular filtration and tubular secretion. Urine concentrations of both sulfamethoxazole and trimethoprim are considerably higher than plasma concentrations in the blood. When administered together as Bactrim, neither sulfamethoxazole nor trimethoprim affects the urinary excretion pattern of the other.

Indications: Chronic urinary tract infections (primarily pyelonephritis and cystitis) due to susceptible organisms (usually *Escherichia coli*, *Klebsiella aerobacter*, *Proteus mirabilis*, and, less frequently, indole-positive proteus species).

Contraindications: Currently, the increasing frequency of resistant organisms limits the usefulness of all antibacterial agents, especially the treatment of chronic and recurrent urinary tract infections.

Warnings: Hypersensitivity to trimethoprim or sulfonamides. Anemia and during the nursing period (see Reproduction section).

Deaths: Deaths associated with the administration of sulfonamides have been reported from hypersensitivity reactions, agranulocytosis, aplastic anemia and other blood dyscrasias. Experience with trimethoprim alone is much more limited, but it has been reported to be associated with hematopoiesis in occasional patients. In elderly patients concurrently receiving certain diuretics, primarily thiazides, an increased incidence of thrombopenia with purpura has been reported.

The presence of clinical signs such as sore throat, fever, pallor, purpura or jaundice may be early indications of serious blood disorders. Complete blood counts should be done frequently in patients receiving Bactrim. If a significant reduction in the count of any formed blood element is noted, Bactrim should be discontinued.

At the present time, there is insufficient clinical information on the use of Bactrim in infants and children under 12 years of age to recommend its use.

Precautions: Bactrim should be given with caution to patients with impaired renal or hepatic function, to those with possible folate deficiency and to those with severe allergy or bronchial asthma. In glucose-6-phosphate dehydrogenase-deficient individuals, hemolysis may occur. This reaction is frequently dose-related. Adequate fluid intake must be maintained in order to prevent crystalluria and stone formation. Urinalyses with careful microscopic examination and renal function tests should be performed during therapy, particularly for those patients with impaired renal function.

Adverse Reactions: For completeness, all major reactions to sulfonamides and to trimethoprim are included below, even though they may not have been reported with Bactrim.

Blood dyscrasias: Agranulocytosis, aplastic anemia, megaloblastic anemia, thrombopenia, leukopenia, hemolytic anemia, purpura, hypoprothrombinemia and methemoglobinemia.

Allergic reactions: Erythema multiforme, Stevens-Johnson syndrome, generalized skin eruptions, epidermal necrolysis, urticaria, serum sickness, pruritus, exfoliative dermatitis, anaphylactoid reactions, periorbital edema, conjunctival and scleral injection, photosensitization, arthralgia and allergic myocarditis.

Gastrointestinal reactions: Glossitis, stomatitis, nausea, emesis, abdominal pains, hepatitis, diarrhea and pancreatitis.

C.N.S. reactions: Headache, peripheral neuritis, mental depression, convulsions, ataxia, hallucinations, tinnitus, vertigo, insomnia, apathy, fatigue, muscle weakness and nervousness.

Miscellaneous reactions: Drug fever, chills, and toxic nephrosis with oliguria and anuria. Periarthritis nodosa and L. E. phenomenon have occurred.

The sulfonamides bear certain chemical similarities to some goitrogens, diuretics (acetazolamide and the thiazides) and oral hypoglycemic agents. Goiter production, diuresis and hypoglycemia have occurred rarely in patients receiving sulfonamides. Cross-sensitivity may exist with these agents. Rats appear to be especially susceptible to the goitrogenic effects of sulfonamides, and long-term administration has produced thyroid malignancies in the species.

Dosage and Administration: Not recommended for use in children under 12 years of age.

The usual adult dosage is two tablets every 12 hours for 10 to 14 days.

For patients with renal impairment:

Creatinine Clearance (ml/min)	Recommended Dosage Regimen
Above 30	Usual standard regimen
15-30	2 tablets every 24 hours
Below 15	Use not recommended

How Supplied: Tablets, containing 80 mg trimethoprim and 400 mg sulfamethoxazole—bottles of 100 and 500; Tel-E-Dose® packages of 1000; Prescription Paks of 40, available singly and in trays of 10. Imprint on tablets: ROCHE 50.

Reproduction Studies: In rats, doses of 533 mg/kg sulfamethoxazole or 200 mg/kg trimethoprim produced teratological effects manifested mainly as cleft palates. The highest dose which did not cause cleft palates in rats was 512 mg/kg sulfamethoxazole or 192 mg/kg trimethoprim when administered separately. In two studies in rats, no teratology was observed when 512 mg/kg of sulfamethoxazole was used in combination with 128 mg/kg of trimethoprim. However, in one study, cleft palates were observed in one litter out of 9 when 355 mg/kg of sulfamethoxazole was used in combination with 88 mg/kg of trimethoprim.

In rabbits, trimethoprim administered by intubation from days 8 to 16 of pregnancy at dosages up to 500 mg/kg resulted in higher incidences of dead and resorbed fetuses, particularly at 500 mg/kg. However, there were no significant drug-related teratological effects.

BACTRIMTM

Each tablet contains 80 mg trimethoprim and 400 mg sulfamethoxazole.

President's Letter

Association of Minnesota Internists

The Association of Minnesota Internists is a component society of the American Society of Internal Medicine, established in 1958 and consisting of specialists in Internal Medicine, Board Certified or Qualified. The national organization, comprising approximately 12,000 members, was originated, and has continued, to provide a forum for education and action by Internists relating to the social, economic, and political forces bearing on medical care. The practical aspects of insuring and monitoring the quality of care and methods of dispensing that care have been of special interest in recent years.

The Association of Minnesota Internists meets frequently through its Executive Committee and meets two to four times annually in general session. Educational meetings have related to numerous items of interest to Internists, from the impact of computerized histories to talks with political figures including Senator Humphrey, Representative Frenzel, and others. The most recent meeting presented a group discussion of prepaid medical health care practices, including representatives from Group Health, the Nicollet Clinic, the St. Louis Park Clinic, Minnesota Blue Cross/Blue Shield, and the Twin City Health Care Development Project. Other meetings have included exchanges of views between practicing Internists and Blue Shield carriers or the Health Care Foundation; others have dealt with internal comparisons of Internists' practices, including an excellent talk by Mr. Millard Mills of Professional Management Midwest. Varying views of members have been heard, discussed, and acted upon with resolutions submitted to our national organization at annual meetings. The Minnesota State Medical Association has recently acted favorably upon a resolution from the Association of Minnesota Internists dealing with assuring the quality of care in various health care delivery programs.

The Association of Minnesota Internists, through its Executive Committee, serves as the representative of its membership in dealing with outside forces in Internal Medicine. Recent issues have included the Foundation for Health Care Evaluation, Minnesota State Legislative Session, the Cancer Detection Center at the University of

Minnesota, the Educational Committee of the Minnesota State Medical Association dealing with recertification procedures, and the Relative Value Sub-Committee of the State Medical Association. Current topics include the PSRO developments in the State, and on-going evaluation of HMO projects.

The officers and Executive Committee of the Minnesota Internists represent physicians from numerous groups and varying viewpoints, having included those from solo and small group private practices, small and large clinics, insurance companies, full-time teachers, and part-time employees of governmental bodies. Hopefully, it is possible that the items dealt upon at meetings have a far wider impact because of the diversity of membership.

Representatives are present at the American Society of Internal Medicine meetings as voting delegates in the spring, at the annual meetings, and at the interim fall meeting, also as an educational project. This year's annual meeting in Chicago related to PSROs with Senator Bennett; Dr. Edwards, the Assistant Secretary of Health in HEW; Dr. Schumacher, Interim Chief of the PSRO, and others as participants. Last year's meeting related to national health insurance with Representative Wilbur Mills, AFL/CIO President Leonard Woodcock, and others. The national organization is also engaged in continuing dialogue with governmental forces and has supplied counsel and help to these, the current Director of PSRO, Dr. Bauer, being a member of the Colorado component and a current governmental contract relating to methods of evaluation of quality of care being two examples. The American Society of Internal Medicine has also intervened with governmental forces when necessary, such as the recent problem relating to pre-admission certification which was to have been brought into effect soon.

The Association of Minnesota Internists welcomes to membership all qualified Internists who are interested in participating in the social and economic aspects of providing quality care to our patients.

WILLIAM J. PAULE, M.D., President
Association of Minnesota Internists

A Phenylketonuric with Superior Intelligence

ROBERT O. FISCH, M.D.,* and PI-NIAN CHANG, M.A.†

THIS REPORT IS to present the case of a phenylketonuric with superior intelligence who has been treated since his early infancy.

Case Report

The patient, a white male infant, was born on September 29, 1968, following an uncomplicated 40-week gestational period. Labor, delivery, and the neonatal course were uneventful. His birthweight was 3628 gm and his length 49.5 cm. He was breastfed. According to the Guthrie Test done on the fourth day of life, his serum-phenylalanine concentration was over 20 mg/100 ml. Repeated tests revealed serum-phenylalanine concentrations between 50 and 55 mg/100 ml, serum-tyrosine concentrations less than 3 mg/100 ml, and the presence of phenylketones and orthohydroxyphenylacetic acid in the urine.

At 26 days of age the child was referred to the Phenylketonuric Clinic at the University of Minnesota Hospitals. A physical examination of the infant revealed blue eyes, blondish hair, a body length of 54.5 cm (45th percentile), a body weight of 4300 gm (40th percentile), and an occipitofrontal circumference of 36.5 cm (50th percentile). According to the laboratory tests, his serum-phenylalanine concentration was 30.4 mg/100 ml and his serum tyrosine concentration less than 3 mg/100 ml. The urine contained phenylpyruvic acid (0.44 micromole/l ml), phenylacetic acid (0.04 micromole/l ml), and orthohydroxyphenylacetic acid (0.04 micromole/l ml). Phenylketonuria was diagnosed and the infant placed on a restricted phenylalanine diet (Lofenalac) beginning October 25, 1968.

Treatment and Outcome

The dietary treatment consisted in variable restrictions of the patient's daily phenylalanine and protein intake. These restrictions, as well as the resultant serum-phenylalanine concentrations are tabulated in the Table for each year of the patient's life.

The patient's growth has been satisfactory since his first visit to our clinic at almost four weeks of age. His most recent weight (at four years, four months) was 19.6 kg (80th percentile), his height 103.6 cm (50th percentile), and his occipitofrontal circumference 51.5 cm (50th percentile). His electroencephalographic records have been

Age	Dietary Management		Laboratory Values	
	Phenylalanine Mg/kg of body weight/day	Protein Gm/kg of body weight/ day	Serum Phenylalanine (Mg 100 ml) Range	Mean
1st Year	50-30	3.8-2.5	1-15	7
2nd Year	30-21.6	3.2-2.6	3.3-19.2	12.4

normal or only slightly abnormal. His bone age has been continually normal for his chronological age. He could sit up alone at five and a half months of age and walk unaided at 11 months of age. He started verbalizing at 13 months of age.

Psychological evaluations have been done annually during the past four and a half years. At seven months of age, he obtained a mental development quotient of 107 on the Bayley Scales of Infant Development; at one and a half years of age, an IQ score of 103 on the Cattell Infant Intelligence Scale, and a SQ score of 122 on the Vineland Social Maturity Scale; at two and a half years of age, an IQ score of 123 on the Stanford Binet Intelligence Scale, Form L-M; and at three years and four months of age, an IQ score of 127 on the Stanford-Binet Intelligence Scale, Form L-M. The most recent psychological evaluation was done in January, 1973. At four years and four months of age, he obtained an IQ score of 142 on the Stanford-Binet Intelligence Scale, Form L-M. His language development, both expressive and comprehensive, appeared very advanced. He used words and sentences at the level of a six-year-old. He even scored on two items, verbal similarities and verbal comprehension, at the seven-year level. His perceptual motor performances, such as maze tracing and identifying missing parts of pictorial objects, were at the six-year level. He obtained these high scores even though his behavior seemed rather restless and fidgety and he found it somewhat difficult to accommodate to external demands.

His home environment is favorable. At the time of his birth, both his parents were 31 years old. The mother had a master's degree in education and was employed. Since intellectual pursuits and achievements are important to her, she started teaching her son how to read, spell, and count before he was two years of age. According to the Wechsler Adult Intelligence Scale, she falls within the superior range of intelligence with a full-scale IQ of 126. The father had a doctor of philosophy degree and was teaching at a college. According to the

Wechsler Adult Intelligence Scale, he falls within the superior range of intelligence with a full-scale IQ of 148. Upon learning that their child was phenylketonuric, the couple decided to have no more children, and the wife has not been pregnant since.

Discussion

This patient is a highly intelligent phenylketonuric who has been treated since early infancy. In the last fifteen years we have treated 101 phenylketonuric children at our clinic. Among these 101 children, there were only 21 whose treatment was begun at less than one month of age. All 21 were evaluated psychologically on the basis of tests given to them annually by the same psychologist. Among these 21 treated children, five have IQs between 100 and 110, and two have IQs above 110 but not exceeding 116. Only this one patient has an IQ above 120.

The outcome of phenylketonuria prior to the dietary treatment was unfavorable, and most phenylketonurics had IQs under 60.^{1,2} During this period few phenylketonurics were reported to have even average intelligence.² Since the institution of the dietary treatment the mental development of phenylketonurics treated early in life has been much better. Recent reports cite numerous phenylketonurics with average intelligence.³⁻⁵ In spite of dietary treatment, most phenylketonurics have been found to perform on psychological tests at a lower level than their unaffected siblings.⁶ There is both theoretical and clinical evidence⁷⁻⁸ suggesting that the phenylketonuric may be damaged *intra utero*, so that his dietary treatment following birth can be only partially successful. A few phenylketonurics treated early in life have performed on psychological tests as well as their unaffected siblings⁵; and one report assumes that phenylketonurics treated early in life may perform better on psychological tests than their unaffected siblings or even their parents.⁹ This assumption, resulting from a study of selected families, remains an unwarranted generalization, and it is questionable in any case whether a serious metabolic disorder like phenylketonuria can ever

be mentally advantageous to its possessor. A few reports dealing with the outcome of both treated and untreated phenylketonurics indicate that a few of them possess higher than average intelligence. These reports fail to mention the ages of the phenylketonurics at the time of the psychological tests and they cite intelligence quotients that include development quotients.^{2,10,11} None of them describes in detail a child with superior intelligence.

As far as we know, our patient is the only phenylketonuric with at least superior intelligence who has been described in detail. The successful outcome of this patient is possibly connected with one or more of the following four factors: (1) The diagnosis was made and the treatment started at an early age. (2) His dietary intake, which has not been severely restricted according to his serum phenylalanine levels, has allowed for a normal growth and more than expected weight gain. (3) His intellectual and social environment difference has been favorable. And (4) there may exist a biochemical enzymatic difference between him and other phenylketonurics. (This assumption, however, is supported neither by the results of blood tests and urinalysis prior to the diet nor by differences in his response to dietary restriction.)

Interestingly, while other phenylketonurics at best maintain their IQs on a certain level, this patient's IQ has been increasing from year to year. One possible explanation for his increasing IQ is that the more advanced tests given to him at a later age allowed for more precise evaluations of his verbal development.

Although it is impossible to generalize from merely one example, it is evident that the dietary treatment of this phenylketonuric patient under favorable circumstances has not been incompatible with the development of superior intelligence. The outcome of this phenylketonuric patient marks an important stage in increasingly successful dietary treatment.

Pneumoretroperitoneum, Pneumomediastinum, and Subcutaneous Emphysema

Complications of Acute, Perforated Diverticulitis

JUAN SUROS, M.D.* and RAYMOND A. LEE, M.D.*

AT LEAST ONE of every four patients with diverticulitis of the colon has a major complication, resulting in an indication for surgery—perforation is responsible for approximately one third of these complications.¹ Typically, the perforation results in a localized pericolic abscess or a fistula, and when the septic process surrounding the perforation is no longer contained, in generalized peritonitis²⁻⁴ with or without pneumoperitoneum. Extraperitoneal perforation of diverticulitis is extremely rare,⁵ and the extension of the intraluminal colonic gas beyond the abdominal area can mimic the most unexpected pathologic condition. Because this complication may occur without a previous history of diverticular disease and may be difficult to relate at first with its primary source, the diagnosis is difficult.

Recently, we have encountered two patients with pneumoretroperitoneum, pneumomediastinum, and subcutaneous emphysema of flank, chest, and neck as a complication of extraperitoneal perforation of acute diverticulitis among a larger number of more common free and local perforations. This experience points once again to the need to be aware of the many manifestations of diverticular disease of the colon and its bizarre complications.

Case Reports

Case 1

An 80-year-old woman fell three years before the present admission and suffered an intertrochanteric fracture of her left hip. Treatment was not successful, and the fracture did not unite. Previously, she had had diverticulosis of the sigmoid colon.

On March 29, 1971, she underwent left total hip

arthroplasty. She did well for the first three postoperative days, and oral feeding was started, but on April 2, she became nauseated, refused to eat because of abdominal pain, and vomited a few times. Physical examination revealed a temperature of 37.8 C (100 F), diminished bowel sounds, and minimal tenderness in the lower abdomen. No masses were felt.

Laboratory studies revealed a leukocyte count of 13,500/cu mm. Values for serum electrolytes and hematocrit and findings on a portable flat abdominal roentgenogram were normal. Conservative treatment with intravenous fluids, intubation, and intravenous antibiotics was started.

On the next day, the abdominal pain and tenderness became more severe and became localized to the left lower abdominal quadrant. In the afternoon of this same day, crepitus was noticed in the neck and supraclavicular regions. Auscultation of the heart also revealed crepitant sounds synchronous with the heart beat. A roentgenographic study confirmed subcutaneous emphysema in the neck, supraclavicular regions, and abdomen, with pneumomediastinum and elevation of the right hemidiaphragm due to free air under it. Several loops of small bowel appeared distended, suggesting mechanical bowel obstruction. A study with contrast medium (gastrographin) revealed that the esophagus was well opacified and normal. The combination of obstruction, free air in the peritoneal cavity, and spreading subcutaneous emphysema, coupled to the clinical symptoms of lower abdominal pain and knowledge of previously proved diverticulosis, made the diagnosis of acute perforated diverticulitis most likely.

When the abdominal cavity was entered, air that was under pressure came out spontaneously. The sigmoid colon was inflamed, indurated, edematous, and attached to an area immediately lateral to the left psoas muscle, where there were signs of a recent extraperitoneal hematoma. At least two small diverticular perforations could be identified. Crepitation could be manually felt along the left psoas muscle and retroperitoneum as high up as the diaphragm. The rest of the colon was normal; its transverse portion was divided and a double-barrel colostomy was established. The left paracolic gutter was drained. The patient became afebrile and recovered

*Mayo Clinic and Mayo Foundation, Rochester, Minnesota.
See editorial, page 772.

without complications. Six months later, left hemicolectomy and coloproctostomy were performed.

Case 2

A 63-year-old man was referred to our clinic on June 25, 1971, because of persistent abdominal symptoms, fever, and shortness of breath. His present condition started 12 days before as acute nephrolithiasis. While receiving an enema in preparation for an excretory urogram, he suddenly experienced severe left lower quadrant abdominal pain, which persisted unchanged during the days that followed. Because there was no response to conservative management and the presence of progressive abdominal distension and rigidity, persistent fever, long history of pulmonary emphysema, and the worrisome appearance of subcutaneous crepitations, he was transferred.

On admission, he was in respiratory distress, and complained of nausea, vomiting, and abdominal discomfort. His temperature was 38.9 C (102 F). Physical examination revealed crepitations over the left flank, left chest wall, both supraclavicular fossae, and neck bilaterally. The abdomen was distended and tender, with some rigidity.

Laboratory studies revealed a leukocyte count of 17,450/cu mm, with a shift to the left. Arterial blood gases showed a P_{O_2} of 48 mm Hg and a P_{CO_2} of 63 mm Hg. Oxygen was given through a nasal cannula (5 L/min), and intermittent positive-pressure breathing, complemented by chest physiotherapy, was begun. Blood and sputum cultures were obtained. Roentgenographic studies confirmed the subcutaneous emphysema and free air in the abdominal cavity. Study of films that the patient brought with him revealed that the free extraperitoneal air had progressed along the left psoas border, left abdominal wall, and left chest wall from June 14 to June 24. A proctoscopic examination revealed that the mucosa was normal up to 21 cm and no angulation was seen.

Conservative treatment was continued, with intravenous fluids, intravenous antibiotics, and intubation, because the urgent problem seemed to be respiratory insufficiency. The patient was observed closely by medical and surgical services, and blood was kept available at all times.

The following day, he improved, being less febrile and short of breath. Two days later, he started to pass gas per rectum and the subcutaneous emphysema seemed to decrease. His abdominal distension and tenderness also diminished. Study after a barium enema on June 28 showed colonic diverticulitis, with perforation of the proximal sigmoid, and an abscess cavity dissecting along the left psoas muscle and extending up as high as the left kidney.

At surgery, during mobilization of the descending colon, on July 2 an abscess containing about 15 ml of purulent material was found lateral to the psoas muscle. A sigmoidectomy and coloproctostomy were performed, and the left paracolic gutter was irrigated with an 0.5% neomycin solution and drained. The patient remained afebrile, had a smooth recovery, and was dismissed on the 12th postoperative day. Pathologic examination of the resected specimen showed acute diverticu-

litis with at least two areas of perforation.

Comment

Sigmoid diverticulitis is the most common inflammatory disease of the colon. Each of our patients had been previously asymptomatic, and the coincidence of diverticular inflammation and extraperitoneal perforation after mechanical trauma (previous hip surgery with pelvic hematoma in Case 1 and enema in Case 2) seems to be more than coincidental, since such a relationship exists in the only case found in the literature.⁵ Morson has pointed out that in colonic diverticulitis the inflammation does not usually affect the bowel wall to any great extent, being primarily an extraluminal process that could be influenced by intraluminal and extraluminal factors. As emphasized by Fleischner and Ming,⁷ the diagnosis of diverticulitis implies the microscopic or macroscopic rupture of a diverticulum. This perforation leads to an inflammatory process predominantly located outside the colonic wall, more accurately referred to as "peridiverticulitis," that may progress to abscess and fistula formation, with an eventual communication with the extraperitoneal space.

In acute diverticulitis, after distal obstruction, perforation, and fistulization into the extraperitoneal space have occurred, peristalsis and increased intra-abdominal and intracolonic pressure could easily force gas along the tissue planes, causing pneumoretroperitoneum, pneumomediastinum, subcutaneous emphysema, and, in general, a gaseous dissection toward areas of low pressure. When the distal obstruction is released, the subcutaneous emphysema disappears in a short while, the lack of uniformity of its reabsorption being due to different tissue conditions. In neither of our patients did the wide diffusion of colonic gas cause any distal infection. The absence of gangrene could be confirmed by the slow progression of the disease, moderate fever, and lack of toxicity; and no surgical attempts were made to drain the subcutaneous gas. More patients with complication of acute diverticulitis are undergoing resection and anastomosis safely in one stage. Previously, a thickened mass in the region of the sigmoid dissuaded surgeons from attempting a primary resection. If this tumefaction represents a small localized abscess in continuity with the bowel, or the thickened bowel itself, resection with or without primary anastomosis, may be carried out safely, especially if there has been a

chance to prepare the bowel. Otherwise exteriorization of the inflamed segment or extensive local drainage, complemented by diversion of the

fecal stream by a transverse colostomy and wide-spectrum antibiotic coverage, seems to be the most logical way to proceed.

Be a physician, Faustus, heap up gold,
 And be eternized for some wondrous cure.
"Summum bonum medicinae sanitas."
 "The end of physic is our body's health."
 Why, Faustus, hast thou not attained that end?
 Is not thy common talk sound aphorisms?
 Are not thy bills hung up as monuments
 Whereby whole cities have escaped the plague,
 And thousand desperate maladies been eased?
 Yet art thou still but Faustus, and a man.
 Wouldst thou make man to live eternally,
 Or, being dead, raise them to life again,
 Then this profession were to be esteemed.
 Physic, farewell.*

Contaminated Pacemaker Lead Wire

Causing Chronic Pseudomonas Septicemia

DAVID KLEVAN*, HORACE H. ZINNEMAN, M.D., WENDELL H. HALL, M.D.
and YOSHIO SAKO, M.D.

A TRANSVENOUS INTRACARDIAC pacemaker electrode became infected two months after insertion. It was embedded in the myocardium of the right ventricle, and attempts to remove it were at first abandoned because arrhythmias arose whenever traction was applied to the electrode wire.

The available alternatives lay between (1) certain disaster with continued bacteremia which was suppressed only temporarily by antibiotic therapy, and (2) possible cure after forcible removal of the infected electrode.

The spectacular outcome of this episode emphasizes the necessity of the removal of such foreign bodies when septicemia is persistent and unresponsive to chemotherapy.

Case Report

A 73-year-old man with a history of several pacemaker implantations was admitted on October 30, 1970 because of recurrent fever. Past medical history included a total laryngectomy and permanent tracheostomy in 1948 for laryngeal squamous cell carcinoma, with one recurrence. In 1952 he developed complete heart block. A demand pacemaker was inserted in November 1967 via the right jugular vein. Because of pacemaker failure, a new pacemaker and electrode wires were installed in July 1969 via the left jugular vein. In September, 1969, the patient suffered infection of the right jugular wound with *Staphylococcus aureus*. The staphylococcal septicemia which ensued was treated with multiple drugs and finally controlled with dicloxacillin. Removal of the pacemaker lead from the right ventricle was attempted in September 1969 but any traction applied to the catheter resulted in atrial fibrillation. Since it was suspected that the electrode was deeply embedded in the myocardium of the right ventricle, the electrode wire was severed at the level of the innominate vein and the electrode terminus was left embedded. The patient was discharged on oral dicloxacillin, which was continued through the spring of 1970.

The patient was seen again on August 11, 1970 for back pain of one month's duration. Vital signs were: temperature 97.8°, pulse 72 and blood pressure 150/80. Physical examination revealed a small amount of purulent

discharge coming from the tracheostomy, a pacemaker pack in the left anterior chest wall and a systolic ejection murmur. Initial white blood count was 11,000/cmm with 80% polymorphonuclear, five stabs, 10 lymphocytes and five monocytes. On August 23 blood cultures yielded *Pseudomonas aeruginosa*. *P. aeruginosa* was also cultured from the sputum. Complaints of severe lower backache led to roentgenologic examination of the spine and the discovery of a defect with surrounding osteoblastic reaction in the body of L₂ vertebra. Needle aspiration confirmed the clinical impression of osteomyelitis. Bacterial culture of the specimen yielded *S. epidermidis*, D Nase negative. Treatment was begun with daily doses of 150 mg gentamicin, 30 gm carbenicillin and 12 gm oxacillin from August 23 through September 13 and then continued with 1 gm dicloxacillin per day. With negative blood cultures and resolution of his fever, the patient was discharged on September 24.

Fever returned in early October and the patient was seen again on October 30, 1970 still on dicloxacillin therapy. The initial blood cultures were negative; later both blood and sputum again yielded *P. aeruginosa*. Fever appeared concurrently. *In vitro* susceptibility was

Figure—Chest Xray on 12-10-70 showing pacemaker with lead wires, as well as cut-off retained lead wire in right side of the heart.

*Senior medical student, University of Minnesota Medical School, Veterans Administration Hospital, Minneapolis, Minnesota.

tested by tube dilutions as shown in the Table, there being some evidence of synergism between gentamicin and carbenicillin. Gentamicin 180 mg per day was started intramuscularly on November 25 and carbenicillin 30 gm per day intravenously on December 4. Both were discontinued on December 8. Chest Xrays (Figure) revealed both the functioning pacemaker and the severed electrode. Since it had become evident that the infection and bacteremia could not be eradicated by antibiotic therapy in the presence of the foreign body, it was again decided to attempt removal of the electrode, this time under direct visualization of the right ventricle by thoracotomy. Surgery for removal of both of the pacemaker leads followed on December 11. The embedded short lead could be removed only by sudden traction, which caused a momentary invagination of the endocardial wall. A 10 mm x 7 mm x 3 mm piece of trabeculae carneae from the right ventricle remained attached to the lead. A 300 cc hemorrhagic pericardial effusion was drained. Temporary epicardial leads were then installed. Separate cultures of the catheter tip and the trabeculae carneae yielded *P. aeruginosa*; cultures of the pericardial effusion were sterile.

The patient was placed on carbenicillin 30 gm per day for seven days and then eight gm per day for seven days. Four days following surgery he became afebrile and remained so for the duration of his hospital stay. He was discharged on January 19, 1971 after installation of permanent pericardial leads connected to the pacemaker pack.

Escape from the pacemaker pulse required readmission in July 1971. A pacemaker pack of higher voltage was inserted. The patient had been afebrile throughout the intervening period, and has since been followed in the outpatient Department for periodic adjustment of the pacemaker. There have been no recurrences of fever through October 1972.

TABLE

Susceptibility of <i>P. aeruginosa</i> to Selected Antibiotics		
	MIC* (mcg/ml)	MBC† (mcg/ml)
carbenicillin	62.5	62.5
gentamicin	.2	1.56
carbenicillin +		
Gentamicin (1:1)	2.0/	3.9/
	.2	.39

MIC* = minimum inhibitory concentration.

MBC† = minimum bactericidal concentration.

Discussion

This case exemplifies the role of foreign bodies in the development and persistence of infections which often continue despite adequate drug therapy.¹ Foreign bodies associated with trauma may cause serious problems if their location makes removal difficult or if they are not suspected. They may be of various materials. Ferguson reports two cases of infected wood fragments in the orbit where the infection remained refractory to all treatment until the wood was removed

surgically.² Fatal *Candida* septicemia refractory to prolonged antibiotic treatment was found at autopsy to be due to a toothpick which was embedded in the right myocardium.³ Infected foreign bodies may consist of suture material, catheters, artificial grafts or orthopedic prostheses. Bahnson reports five cases of infected silk sutures placed in the heart and great vessels, which were refractory to antibiotic therapy until successfully treated by surgical removal.⁴ Amoury reports that, in his series of 13 infected intracardiac prostheses treated with antibiotics, nine died and two infections were clinically suppressed by long term antibiotics, but one was suppressed and then cured surgically. Only one was cured by a six weeks course of antibiotics alone. The latter was the only case due to *Serratia marcescens*, all others were caused by *Staphylococcus epidermidis*.⁵ A series of 51 similar cases reported by Bainbridge resulted in survival of 10 of 43 patients under medical therapy and three out of eight with surgical treatment.⁶ He does not mention whether survival in those treated medically represented continuous suppression or cure. Littlefield reported a case of an infected aortic valve prosthesis where antibiotics did not suppress the septicemia but surgery resulted in cure.⁷ Three cases of infected prosthetic arteriovenous shunts placed for maintenance hemodialysis, were reported by Goodwin and required removal of the functioning shunts.⁸ Several authors conclude that infection of ventriculoatriostomy catheters and valves can be suppressed by antibiotics but cured only with removal of the offending foreign body.⁹⁻¹¹ The same conclusion has been reached in reports of catheter emboli to the heart and pulmonary artery.¹²⁻¹³ Waissner reports septic pulmonary emboli arising from a transvenous cardiac pacemaker, cured by a combination of antibiotics and removal of the entire pacemaker apparatus.¹⁴ In a series of 12 infected pacemakers, Firor had three deaths due to infection, all occurring in the first group of six where the pacemakers were not removed. A regime including removal of all foreign material resulted in cures of the next six cases.

Foreign bodies greatly lower the number of bacteria necessary to cause infection, both in animals¹⁶⁻¹⁷ and man.¹⁸⁻¹⁹ This fact has been used to develop an experimental model for production of both right and left sided endocarditis.²⁰⁻²¹ No adequate explanation of this phenomenon has yet been verified. McDermott also emphasized the

adaptability of the infective microorganism in its interaction with various host environments, including presence of antibiotics.²² Drug penetration often does occur. Antimicrobial inactivation by purulent material is thought not to be important.¹ MacLennan noted that clostridial gas gangrene

following penetrating wounds often is due to the presence in the wound of foreign bodies, such as bits of clothing, particles of dirt and fragments of metal and wood.²³

The removal of any infected foreign material appears imperative for cure of serious infection even if this involves great risks.

The Aortocranial Vessels

The Transfemoral Approach

Analysis of Results and Complications

EDWARD L. TALBERTH, M.D.* and LAWRENCE H. A. GOLD, M.D.†

DURING THE PAST decade the use of the transfemoral approach for selective catheterization of the brachiocephalic arteries has gradually become more popular. While the major emphasis has been on selective vertebral arteriograms,^{1,7} the versatility of the procedure lends itself to rapid examination of the carotid system as well. Many physicians now perform the majority of their carotid studies via the femoral route with excellent results. In our institution the incidence of transfemoral selective catheter studies has increased from 5.2% of all cerebral angiographic procedures in 1969 to 20.4% in 1972.

This paper is an analysis of 230 transfemoral catheterizations of the brachiocephalic arteries performed by the Neuroradiology section of the Department of Radiology at the University of Minnesota Hospitals from January 1969 to April 1972. The examinations included not only vertebral and carotid angiography, but also spinal cord angiography, arch aortography and selective subclavian angiography. The average age of the patients was 45.8 years. There were 113 males and 117 females.

Technique

After sedation with Seconal, Demerol, and atropine and appropriate cleansing and draping of the groin area, 10 cc. of 1% Xylocaine are infiltrated into the skin and around the femoral artery. The femoral puncture is made with an Amplatz 19 gauge needle with a Teflon sheath. Using the Seldinger technique, a Teflon coated 100 cm. guide wire is passed into the abdominal aorta over which a Cordis No. 8 French "head-hunter" catheter is passed. Following removal of the guide wire, the catheter is flushed with heparinized saline (1000 units per 500 ml. saline). The catheter

is then advanced up into the aortic arch under fluoroscopic control.

In most adult patients the combination of the "head-hunter" catheter, and occasionally the use of a Teflon coated "J" shaped or graduated stiffness guide wire is sufficient to catheterize the carotid and vertebral arteries. Very rarely, a Cordis "shepherd's crook" catheter may be required in patients with a very tortuous aorta. After entering the common carotid artery the catheter is advanced just proximal to its bifurcation and an injection is made with 12 cc. contrast medium using an Amplatz injector under 45 pounds per square inch of pressure. The usual filming sequence is two films per second for three seconds and one film per second for four seconds, a total of ten exposures over seven seconds. Immediately following the injection the catheter is removed from the carotid artery. If selective visualization of the external and internal carotid arteries are needed, the catheter is maneuvered into these vessels and further injections of contrast medium are made. For vertebral angiography the origins of both vertebral arteries are visualized utilizing injections into the subclavian arteries under fluoroscopic control. The larger vertebral artery is selected for injection as this reduces the risk of arterial occlusion by the catheter. In order to keep the time the catheter is in the vertebral artery to a minimum the tip of the catheter is first placed at the orifice of the vessel and the patient's head positioned for angiography. Under fluoroscopic control the catheter is then advanced into the vertebral artery. The patient is then rapidly positioned on the film changers and a forceful hand injection of 8 cc. of contrast medium is made into the artery. The catheter is immediately withdrawn into the aortic arch and flushed with heparinized saline.

After reviewing the films to determine technical quality and the need for additional views, the

*Fellow in Neuroradiology, Department of Radiology, University of Minnesota Hospitals.
†Associate Professor, Department of Radiology, University of Minnesota Hospitals.

catheter is removed from the femoral artery. The technique described by Jeffrey² is used. This involves suction on the catheter during removal to extract any adherent thrombus out of the puncture site. The artery is also permitted to bleed for approximately one second in order to express any possible clot. If no bleeding occurs after removal of the catheter massage of the vessel proximal to the puncture site may express a clot. Pressure is then placed on the femoral artery for six to ten minutes and the puncture site is observed for several additional minutes to make certain bleeding has ceased. If the dorsalis pedis and/or the posterior tibial pulses are diminished from their preoperative status 10 cc. of 1% Xylocaine are infiltrated around the artery to relieve any spasm.

Presently all the intracranial studies are routinely magnified in both frontal and lateral planes using simultaneous biplane exposures.³ The carotid angiograms are magnified 1.5 times and the vertebral angiograms 2.0 times.

Eight spinal cord angiograms were performed via the transfemoral route, in search of a spinal cord arteriovenous malformation. There were four arch aortograms and three subclavian or innominate angiograms. Eight patients had combined carotid and subclavian angiograms. The aortograms and innominate and subclavian angiograms were done primarily for atherosclerotic disease and/or vertebrobasilar insufficiency.

The breakdown of examinations by age group is shown in Table 1. The relatively large number in the 50-60 year group reflects those patients being evaluated for atherosclerotic disease in the carotid arteries.

Results

Analysis of the number and type of studies performed is shown in Table 2.

In a majority of patients visualization of multiple vessels was needed. Relatively few arch studies were done. When it was desired to demonstrate the origin of the great vessels, an injection of contrast medium was performed proximal to the orifice of the vessel. In our experience this gives excellent visualization of the origin of the brachiocephalic vessels. The origin of the left carotid artery can be visualized with an injection at its origin and compression of the left carotid artery. This results in reflux down the carotid into the aortic arch.

We have attempted to analyze the number of instances where desired visualization of a vessel could not be obtained. An attempt was made to catheterize 320 carotid arteries in 180 patients and was unsuccessful in 16 instances, a failure rate of five percent. In nine cases the right carotid could not be catheterized and in seven cases the left carotid could not be entered. The average age of these patients was 61 years. The high frequency of very tortuous, atherosclerotic aorta in this age group often makes catheterization extremely difficult. All of these patients had subsequent visualization of the carotid artery by either direct puncture or retrograde brachial angiography.

Attempts were made to catheterize a vertebral artery 188 times. In only three cases was the study unsuccessful, a failure rate of 1.6%. The average age of the three patients was 65 years.

The left vertebral was studied three times as often as the right. This is because it was easier to enter and often larger than the right. Both vertebral arteries were examined in 19 instances.

There were no cases where the catheter could not be passed beyond the iliac arteries into the thoracic aorta. In one instance the opposite femoral artery had to be punctured because of inability to pass the guide wire beyond the right iliac artery.

Complications

We have divided the complications of the transfemoral approach to the brachiocephalic vessels into two categories: neurologic and femoral. There were no deaths in this series.

Neurologic Complications

Neurologic complications occurred in four patients.

tients or 1.7%. The average age of these patients was 58 years. The findings are summarized in Table 3.

TABLE 3

Neurological Complications	No. of Cases
Hemiparesis clearing within several hours	2
Pronounced dysphasia and decreased sensorium	1
Loss of vision, confusion	1
Total	4

The first patient was a 57-year-old woman with angina pectoris and transient ischemic attacks on the right side. She experienced angina pectoris during the study. Angiography demonstrated an 80% occlusion of the right common carotid bifurcation. Three hours after the completion of the procedure she developed a profound left hemiparesis which cleared completely in ten minutes. It is questionable whether the hemiparesis was related to the angiography since it occurred several hours after completion of the study.

The second patient was a 65-year-old woman who underwent examination of her right and left carotid and left vertebral arteries following placement of a Selverstone clamp on the right common carotid artery for an intracranial aneurysm. Angiography demonstrated complete occlusion of the right common carotid artery from the clamp with poor collateral circulation to the right middle cerebral artery. Shortly after completion of the study she developed pronounced dysphasia, confusion and decreased sensorium. After several hours she gradually improved to her preangiogram condition. It may be that dilution of blood by contrast medium in an already partially hypoxic area contributed to the problem. Kutt and Verbeily⁴ have suggested that during injection up to two-thirds of the fluid in the carotid artery may briefly consist of contrast media. In individuals whose circulation is already compromised this temporary reduction in oxygen could be of clinical significance.

The third patient was a 58-year-old man who entered the hospital following the sudden onset of a left hemiparesis. He underwent right common carotid and left vertebral arteriography which revealed a 90% stenosis of the right internal carotid artery and an occlusion of a right middle cerebral branch with retrograde collateral filling. After the vertebral artery injection, the patient became confused and disoriented with a partial loss of vision. There was gradual improvement

over the next two days with return of function to his preangiogram status.

The fourth patient was a 54-year-old male admitted following a subarachnoid hemorrhage. There was no history of hypertension. A left vertebral angiogram was performed first, followed by a right common carotid study. The films demonstrated a basilar artery aneurysm but no evidence of occlusion in the right carotid circulation. Toward the end of the procedure the patient developed a left hemiparesis. An intravenous infusion of Rheomacrodex was started with gradual regression of the symptoms over several hours.

Femoral Complications

The femoral complications we experienced were all related to the femoral artery through which the catheter was passed (Table 4). There were five cases of femoral artery thrombosis (an incidence of 2.1%), six cases of large groin hematomas (2.6%), and seven instances of decreased peripheral pulses which did not progress to thrombosis and which did not require surgery (3.1%).

TABLE 4

Femoral Complications	No. of Cases
Femoral Artery Thrombosis	5
Large Groin Hematoma	6
Diminished Peripheral Pulses	7
Total	18

All five cases of femoral thrombosis had surgical exploration with a Fogarty catheter under local anesthesia followed by complete recovery. There was no loss of limb or residual claudication. The average age of the five patients was 36 years. One patient was two and a half years old. All instances of femoral thrombosis occurred before we started using the method of removing intra-arterial clots advocated by Jeffrey.²

Analysis of the five cases showed that four of the five patients were either paraplegic or hemiparetic before the procedure. This implies that since there was very limited use of the lower extremities, the muscular tone in those extremities was poor and most probably the same was true for the arteries supplying those muscles. Two of the patients also had severe atherosclerosis affecting the femoral artery.

Lang⁵ in his analysis of complication of 11,000 femoral catheterizations noted that arterial thrombosis appeared to be associated with poor vascular fitness of the individual. Other predisposing factors in his series were low output failure and arteriosclerotic vascular changes.

There was some correlation between the occurrence of large groin hematomas and diminished peripheral pulses and the length and difficulty of the procedure. Large groin hematomas were encountered in six patients (2.6%). Four of these had prolonged examinations because of tortuosity of the brachiocephalic vessels. One patient was on anticoagulants. Three patients were markedly hypertensive, making control of bleeding from the femoral artery quite difficult. The hematomas did not require evacuation nor did they result in hypotension or blood transfusion. There was no case of false aneurysm formation associated with this complication. Seven patients, an incidence of 3%, had a mild to moderate decrease in the peripheral pulses at the end of the procedure. The average age was 45 years, and affected six females and one male. Again, prolonged studies with considerable manipulation of the catheter seemed to have enhanced the possibility of arterial spasm. The diminished peripheral pulses may also result from small platelet thrombi which adhere to the catheter and then remain in the arterial lumen when the catheter is removed. These small clots would then be free to migrate to small distal vessels. The problem of small platelet thrombi left in the artery is partially overcome by the technique of Jeffrey.² Young patients, particularly females, tend to have more arterial spasm with less manipulation of the catheter than older patients. The treatment in cases of diminished peripheral pulses is to infiltrate the tissues about the femoral artery with Xylocaine. This usually relieves the spasm and results in good peripheral pulses. The patient's leg is observed closely over the next six hours.

Indications and Contraindications

The indications for the transfemoral approach to the brachiocephalic vessels are listed in Table 5. There are several possible reasons why a carotid artery cannot be punctured percutaneously in the neck such as: when the patient is extremely obese, when a hematoma is present in the neck from a previous attempt at carotid puncture, when there has been a subintimal injection of contrast medium, or when there has been previous surgery or irradiation of the neck making percutaneous puncture more difficult, or simply when the carotid artery cannot be punctured for any reason.

When it is necessary to visualize multiple vessels, usually in a patient with subarachnoid hemor-

rhage without focal neurologic findings, it is much easier for the patient and faster to approach these vessels from the femoral route with a catheter rather than to do three punctures percutaneously in the neck and arm (bilateral brachial and left carotid angiograms). In patients suspected of having an arteriovenous malformation, the malformations are frequently fed by multiple vessels including branches of the external carotid, and it is necessary to visualize the entire vascular supply to the malformation.

In patients suspected of having cerebrovascular atherosclerotic disease where surgical intervention is being considered, it is often desirable to visualize multiple vessels. There is some increased risk to direct carotid puncture as the puncture may be made at the site of an already severely narrowed artery or at the site of a large ulcerated atheromatous plaque. For these reasons, the catheter approach is more desirable, since the catheter placement is not a blind procedure, but done under fluoroscopy and the injection of contrast medium is made proximal to the usual site of the patient's occlusive disease. Also, the catheter approach will allow visualization of the origins of the carotid and vertebral arteries. In all cases the catheter approach is faster, easier and requires less contrast medium than visualizing the origins of the vessels from bilateral brachial injections.

To visualize the posterior fossa either for tumor, aneurysm, malformation or occlusive disease, selective vertebral arteriography is essential and is best done with the catheter approach rather than a direct vertebral artery puncture.

Finally, if it is necessary to do selective injections into smaller branches of the brachiocephalic arteries for any reason, this can only be done with a catheter.

There are several relative contraindications to the transfemoral approach. Elderly patients over the age of 65 usually will have extremely tortuous vessels at the aortic bifurcation and in the aortic arch which makes the catheter approach much

TABLE 5

3. Posterior fossa angiogram desirable for any reason.
4. Selective injections into small vessels is necessary.
 - a. External carotid.
 - b. Thyrocervical trunk.
 - c. Costocervical trunk.

more difficult and increases the risk of neurologic and femoral complications. However, age alone should not be an absolute contraindication and each case must be evaluated on its own merits by weighing the possible complications against the desirability of obtaining a complete and satisfactory study.

Another contraindication to the catheter approach is the patient with severe peripheral vascular disease in the legs with or without absent peripheral pulses in the foot. These patients probably should not have a catheter approach from the femoral artery as there would be a significant danger of severe complications in the leg. The axillary approach, with a catheter, is often a satisfactory alternative.

Discussion

Recent articles^{1,6,7,8} on the various techniques available for visualization of the brachiocephalic vessels have all stressed the great versatility which the femoral route allows, while at the same time being comparatively free of serious complications. Using the femoral approach our success rate of 95% in carotid arteriography and 98% in vertebral studies compares very favorably with similar reported series.

Examination of the vertebral arteries is now almost completely done with the transfemoral technique. If the vertebral artery cannot be catheterized, then a left or right retrograde brachial study is performed. The brachial study however often results in inadequate visualization of the posterior fossa vessels, does not visualize the contralateral posterior inferior cerebellar artery, and gives insufficient information for the evaluation of tumors of the posterior fossa. It merely rules out very gross abnormalities.

We were able to obtain completely successful examinations of the posterior fossa in 98% of patients. The main difficulty was very tortuous vessels in elderly patients. The average age of the failures was 65 years.

The issue of most common concern is that of the neurologic sequelae of angiography. Of the four patients with neurologic complications in this series, two experienced hemiparesis, one had loss of vision and one suffered decreased sensorium and dysphasia. All these symptoms cleared within several minutes to several days, with no permanent neurologic deficit.

In our series there was not a significantly greater

number of neurologic problems with the vertebral studies as compared to the carotid studies. Other authors^{1,9} have commented on the greater risk encountered with posterior fossa angiography.

We have minimized the risk of posterior fossa angiography in several ways: by injecting into the larger vertebral artery so that the catheter does not obstruct the vertebral artery, by doing a hand injection of a small volume (8 cc.) of contrast medium rather than using a power injection, by having the x-ray technologist being ready to take the radiographs before the catheter is placed in the vertebral artery and by immediately withdrawing the catheter from the vertebral artery once the injection has been completed.

There are a number of theories regarding the etiology of neurological complications. Adams¹⁰ suggests that emboli from foreign substances such as cotton fibers may be responsible. Wishart¹¹ raises the possibility of the catheter tip dislodging atheromatous plaques from the arterial wall. Another possibility is the dislodging of small platelet emboli from the end and sides of the catheter during manipulation of the catheter. Finally, Kutt and Verbely⁴ believe that part of the problem is a relative ischemia produced by diluting the blood with contrast medium during the injection. Normally, this would not cause any problems. However, in a patient who already has diminished cerebral blood flow because of atherosclerosis, this dilution may be critical.

Both the neurological and femoral complications can be kept to a minimum by following certain basic principles. The catheter study must be done quickly and efficiently, with the radiologist and the x-ray technologist working as a team. The procedure should never take more than one and a half hours to complete. The longer the procedure, the higher the incidence of complications. The catheter should only very rarely be changed since this prolongs the procedure and increases the risk of femoral complications. Thrombus material on the sides of the catheter is peeled off as the catheter is exchanged and this thrombus cannot be retrieved. The catheter should be removed from the vessel immediately following the injection. The amount of contrast medium used should be kept to a minimum and should not exceed a total volume of 200 cc. The patient must be monitored frequently during the study by the radiologist for any changes in sensorium, reflexes, blood pressure, and ability to move his extremities. Any

change in the patient's condition should result in termination of the procedure.

The technique of Jeffrey² should be employed. It is our opinion that the removal of thrombi stripped from the catheter during its removal significantly decreases the femoral complications.

Summary

The technique, indications, and results of the catheter approach to the aortocranial vessels in 230 patients have been described and the com-

plications of the procedures investigated. Different theories as to the etiology of these complications were suggested and possible methods of prevention described. A success rate of 95% for carotid artery examinations and 98% for vertebral artery studies was achieved. The overall serious complication rate was low and likely will continue to decline in the future as more studies are performed and new techniques and materials are developed.

Cover Painting "Split Rock Lighthouse"

Dr. Tague Chisholm, a pediatric surgeon, has been interested in doodling and drawing since childhood. He says that many of his professional patient files in the office have diagrams and drawings rather than words. Other than mechanical drawing in high school, Dr. Chisholm has never had any formal art instruction. His real interest in painting began following an automobile accident in 1965. During this time he tried line drawings, charcoals, water colors, until one day David Feigal came to see him stating that it was time to start real painting and provided him with a box of oils. Because of patient complaints in the next rooms of the oil odors, Dr. Chisholm dropped oil painting and pursued water colors.

In 1971 he heard that in-service art lessons were being offered at North Memorial Hospital and went up to their classes for eight weeks. That is where he learned about Acrylics without their odor and with their fantastic qualities for painting.

Each year during his annual vacation on Nantucket Island, Dr. Chisholm paints one picture every other day for the whole month's vacation, and as a result has earned the title of "The August Painter."

Dr. Chisholm wrote the Editors: "Most of the time I like to paint directly from my sight. I have never painted from a projected picture of a Kodachrome slide. My subjects are mostly landscapes, seascapes, waterscapes, and architectural forms. I'm especially fond of lighthouses. I now have done nearly two dozen of them from Portland, Oregon to Portland, Maine. Lighthouses make a fascinating study since they are a disappearing segment of Americana. Almost all have had their lights turned out. Most are no longer manned by a lighthouse keeper and a good many have been demolished and torn down. I find the story of the Split Rock Lighthouse on the North Shore extremely fascinating. This is one of the parts of Minnesota which I love the most; it's very much like where I come from in the State of Maine."

The Cell Separator

A Continuous Flow Centrifuge for Blood Component Collection

L. CRANDALL, M.D.*, I. E. FORTUNY, M.D.,† J. McCULLOUGH, M.D.‡
and B. J. KENNEDY, M.D.¶

IN THE PRACTICE of clinical medicine, physicians may be confronted with situations where either the administration or removal of single blood components is of the utmost importance. In the past, limited technology has made such a procedure physiologically impractical. The introduction of plastic bags for blood collection made it possible to produce several products from a single unit of blood. Later, the technique of plasmapheresis improved the ability of the blood bank to collect plasma without the limitations of red cell loss incurred by the donor. However, plasmapheresis, being a system of intermittent blood collection and return to the donor, made the processing of large volumes of donor blood impractical.

Recently, a cell separator has been developed to process large quantities of whole blood in a closed, sterile, continuous flow system. The desired blood component, or components, are removed and the remaining blood returned to the donor. This instrument, which was devised by investigators at the National Cancer Institute and the Systems Development Division of the International Business Machines Corporation, has been established as safe for clinical use by both animal experimentations and human use.¹⁻⁶ Two models of this instrument now available are the NCI-IBM Blood Cell Separator and the Aminco Celltrifuge (American Instrument Co.).

An Aminco Celltrifuge was added to the support facilities of the Masonic Leukemia Treatment Center in the Masonic Memorial Hospital of the University of Minnesota Health Sciences. Invest-

igations of its applicability to clinical oncology were undertaken by the Section of Medical Oncology and the Blood Bank.

The Celltrifuge

In a closed, sterile system an uninterrupted flow of blood is maintained in a constant force of gravity while collection of individual blood components is in progress. This continuous flow makes the separation of components of almost equal density (red blood cells and plasma) possible as well as the separation of smaller fractions of intermediate density (leukocytes and platelets). Red cells, plasma, leukocytes and platelets, individually or in a desired combination, can be collected or returned to the donor in a continuous flow of several times the donor's blood volume.

The size and shape of the machine can be seen in Figure 1. A central drive well lodges the

centrifuge bowl. Peristaltic pumps are used to draw the red cells, buffy coat and plasma through the system while different pumps remove the component to be separated during the procedure. The centrifuge bowl (Figure 2-A) is made of a heat resistant polycarbonate plastic. The center core has a central flow path four inches long and 0.04 inches wide and an outer (Figure 2-B) flow path with a flared portion where the blood components separate into three distinct layers; an outer red cell layer, a middle buffy coat layer, and an inner plasma-platelet layer. The effective radius of the bowl is 2.5 inches. The bowl is tightly closed by a clear plastic cover (Figure 2-C) containing three exit ports which collect the contents of the three blood layers. The clear plastic cover allows the operator to observe the actual separation of the blood components and to adjust the system to give optimum collection.

The most critical part of the instrument is made up of two components, one a rotating multichanneled flat ceramic seal (Figure 2-D) and the other a stainless stationary portion (Figure 2-E) which contains the ports of entry and exit of the blood flowing through the centrifuge bowl. The surfaces of the seals are held to a flatness of 30×10^{-6} of an inch and lubricated with saline solution, making the system hemolysis free. The assembled bowl is shown in Figure 2-A.

Procedure

The instrument is primed with acid-citrate-dextrose (ACD) anticoagulant solution to elimi-

nate all air from the system. The total volume contained in the tubing lines and centrifuge bowl is 150 ml. At the end of the procedure all but 50-70 cc of blood, which cannot be pumped out of the bowl, returns to the donor.

The donor is connected to the machine by ante-cubital venous punctures (gauge 14-15). A bolus of 2,000 units of heparin is given when the needles are in place. An ACD drip of 1 ml. per 20 ml. of whole blood plus heparin-saline at a rate of 15 units per minute is delivered to the inflow line leading to the machine. The blood flow can be maintained between 40-65 ml per minute depending on the size of the venipuncture needles. The procedure is usually carried out during a four hour period at which time a total of 400-500 cc of ACD solution and 4,000-4,500 units of heparin have been given to the donor.

Clinical Uses

Preliminary investigations have explored the uses of this apparatus. Certainly as a source of variable blood components, it offers a material source for basic research studies dealing with specific blood cell components. Although currently regarded as an investigative procedure, early results already are defining the potential clinical uses of the machine and projections are being made as to its role as a service unit in clinical medicine.

Leukapheresis

Leukapheresis is the removal of leukocytes from either normal donors or from patients with acute or chronic leukemia. The collection efficiency for leukocytes is variable within a range of 25-35% recovery, which in normal donors represents a granulocyte mass of $0.8-1.63 \times 10^{10}$ granulocytes in a volume of 250-300 ml. Granulocyte recovery from patients with chronic myelogenous leukemia varies between $0.4-3.11 \times 10^{11}$ cells in a four hour run.

Thus, two clinical uses for granulocytes are evident: granulocyte transfusion to leukopenic patients and leukocyte removal in the management of patients with chronic leukemia.

In studies of granulocyte transfusion to patients with acute leukemia undergoing chemotherapy remission induction, it has been shown that lysis of fever occurs following granulocyte transfusion and that the chances of such improvements are directly related to the number of transfused granulocytes.^{5,7}

Fig. 2—Assembled centrifuge bowl (A); ceramic bowl (B); plastic cover (C); ceramic seal (D) and stationary stainless steel port (E).

In measuring the increase of peripheral leukocyte counts following granulocyte transfusion, there is a higher recovery of the transfused granulocytes when the donors are blood relatives of the leukopenic recipient.⁸ When the donor and patient are identical twins the mean recovery of transfused granulocytes is 43.0%. This ratio decreases to 27.0% when siblings are used and drops further to 11.8% when parents are used.

Although the recovery of granulocytes from non-related donors is approximately 5%, it has been claimed that lysis of fever does occur following such transfusion to acute leukemic patients undergoing chemotherapy for induction of remission of the leukemia.

Current investigations are directed toward determining the fate of transfused granulocytes by studying their survival in the peripheral blood, and by stimulating their release from the bone marrow and marginal pools. It is further apparent that careful leukocyte typing will be necessary between donor and recipient similar to that now performed for transfusion of red blood cells.

It has been proposed that leukapheresis as an initial management of the symptomatic patient with chronic leukemia may allow a return to a symptom free situation as a result of the reduction of leukocyte mass and organomegaly; thus postponing the use of chemotherapy.⁹⁻¹⁴ This proposal is based upon the assumption that in chronic leukemia leukocytes progressively accumulate either because of increased marrow production, prolonged leukocyte survival and/or an overwhelmed removal mechanism.¹⁰

Our studies on a limited number of patients suggest that there are two different populations of chronic leukemia patients, only one of which can benefit from leukapheresis. Appropriate leukokinetic studies are being incorporated to determine the type of patient and the time at which leukapheresis may be a valuable therapeutic method in the overall management of chronic

leukemia.

Plateletpheresis

Collection of platelets can be accomplished efficiently by standard blood bank techniques and the celltrifuge offers no practical advantage. However, platelet collection can be efficiently carried out during leukapheresis; thus providing the Blood Bank with another source of platelets which are in great demand during the initial treatment period of acute leukemia.

Plasmapheresis

Plasma exchange by the use of the cell separator has been shown to be safe, rapid and with clinical benefits (replacing globulins and albumin) which surpass conventional plasmapheresis.¹¹ Thus, it may be of value in the treatment of patients with paraproteinemias, hepatic coma,¹² and in patients with large amounts of circulating antibodies (i.e. hemophiliacs with large amounts of anti-factor VIII antibodies.¹³ Although introduced for the support of patients with acute leukemia, it is already apparent this apparatus will have a wide variety of clinical uses beyond those required in oncology. Such investigations clearly emphasize that cancer research extends its benefits to all medicine fields.

Summary

The cell separator offers a safe, rapid and effective method for procurement of blood components, especially leukocytes, platelets and plasma for transfusion. The major clinical uses are leukocyte collection for transfusion to patients with leukopenia, and leukocyte removal in the management of patients with chronic leukemia. The role of leukocyte transfusion in infected patients with leukopenia remains to be clarified as does the treatment of chronic leukemia by cell removal alone. The cell separator is an ideal instrument for the rapid exchange of plasma in patients with paraproteinemia, hepatic coma or circulating antibodies.

Sequential Obstetric-Pediatric Intensive Care

RICHARD S. SHELDON, M.D.*

DURING THE PAST FEW YEARS, increased attention has been placed on fetal and neonatal salvage. This attention was stimulated by international reports that compared perinatal mortality data among various countries. The data from the United States ranked well down on the list.¹

Spokesmen in the field of obstetrics have re-emphasized the need for close prenatal observation, testing suspected abnormalities during prenatal care, and fetal monitoring during labor.²⁻⁴ Pediatricians continue to emphasize the basics of infant body temperature, early observation of acid-base balance, and exact blood-oxygen saturation. Strides also have been taken to better manage respiratory distress in the newborn.^{5,6} This stimulated interest in pregnant women and newborn infants appears to have decreased perinatal wastage when individual specialized care has been instituted.

This paper concerns the problems in caring for pregnant women and their offspring. Some of the potential areas in the care of obstetric patients are reviewed in which early recognition and expedient management can provide the best chance of survival for the newborn infant—management that can be provided by teamwork involving obstetric-physician and pediatric-physician.

Most of us recall the time when the obstetric-physician delivered a baby and, when he noticed that the baby was ill, he would enlist the services of a pediatric-physician. Until recently the ability to manage the newborn was handicapped by a lack of new knowledge in the care of the newborn. Vital functions of the sick infant are now observed with sophisticated monitoring equipment; breathing can be assisted with continuous positive airway pressure respirators; and blood pH and oxygen saturation can be managed with greater skill. Some infants who previously were expected to die now live.⁶

The care of the newborn infant has become the

responsibility of an obstetric-pediatric team. The obstetric-physician attempts to anticipate the premature or sick infant and requests that a pediatric physician be present at delivery, who then can provide the necessary specialized care. When problems with the newborn are anticipated and special care facilities are not available immediately, arrangements can be made for the mother to deliver her baby in a location where specialized care is available, thus preventing any time delay between delivery and treatment of the newborn.

Most of the high-risk situations can be anticipated. The high-risk conditions can be categorized into those occurring: (1) during prenatal care and (2) during labor. Conditions that can be recognized during prenatal care which may generate high-risk infants at birth are Rh sensitization, diabetes mellitus, preeclampsia, maternal infections, "small-for-dates" babies, previous stillborn, twin pregnancy, and breech presentation. Conditions that can be recognized during labor which may deliver stressed infants are premature rupture of membranes, premature labor, prolonged labor, fetal distress (heart rate deceleration and meconium staining), third trimester bleeding, and malpresentations.

Each of these conditions can produce intrauterine death if the possibility of physiologic deterioration is not observed both during pregnancy and while the mother is in labor. And each of these conditions holds the latent hazards of prematurity, sepsis, and physiologic stress for the infant or a combination of these conditions at the time of birth.

At the present time, institutions that staff high-risk pregnancy centers and infant intensive care units have several testing procedures available to help observe and manage the high-risk pregnancy patients on both outpatient and inpatient bases. Physicians in outlying communities may take advantage of these procedures by sending specimens to regional laboratory facilities or by referring the patient either for a specific test or for a battery of

*Consultant, Department of Obstetrics and Gynecology, Mayo Clinic and Mayo Foundation, Rochester, Minnesota.
See editorial, page 773.

tests to help establish the status of the pregnant patient. These procedures include 24-hour urine estriol determination, amniocentesis for spectrophotometric analysis and maturity screening, intra-uterine transfusions, and ultrasound determinations, as well as consultation regarding other possible medical problems.

Depending on the patient's problem, the physician may manage the patient in the home community or refer her for high-risk pregnancy management if monitoring equipment during labor and the availability of an infant intensive care facility seem advisable.

The fetal heart rate monitor has introduced a new parameter to the care of the high-risk pregnant patient at term and during labor. The beat-to-beat observation of the fetal heart rate provides the best available record of the status of the fetus during labor.³ The fetal heart beats and the frequency and duration of contractions of patients with intact membranes can be observed by the use of, respectively, external ultrasound transducers and the tocodynamometer. This type of observation is of particular importance when a high-risk infant is recognized before the onset of labor.

If there is doubt that the fetus can tolerate the rigors of labor, this can be challenged by the use of an oxytocin infusion to determine whether decelerated heart-rate patterns develop with contractions. Positive evidence of fetal distress such as this indicates that delivery by cesarean section is advisable if labor is expected to be long or vaginal delivery traumatic.

When a high-risk patient is admitted in labor, the external monitoring equipment can be used until the membranes rupture or if rupture of the membranes is inadvisable. When membranes are ruptured, direct fetal monitoring can be obtained with the fetal scalp electrode and the intra-uterine pressure catheter. Because electric interference is almost totally eliminated with the direct monitoring equipment, it yields the most valid information. The intra-uterine pressure catheter not only detects the frequency and duration of contractions but also determines the strength of each contraction.

On occasion fetal distress becomes evident during labor either by fetal heart rate deceleration or by the presence of meconium staining. If delivery is not imminent, the extent of fetal distress can be determined by the sampling of fetal scalp blood.⁴ Examples of this management are illus-

trated in the following situations.

Rh Sensitization

The Rh-sensitized patient is observed for increasing antibody titers during pregnancy. If titers increase significantly, amniocentesis for spectrophotometric analysis of bilirubin is used to direct the management of the pregnancy. Arrangements for intra-uterine transfusion by a qualified obstetrician can be made when indicated.

Diabetes

The insulin-dependent diabetic patient is managed during the early months of pregnancy by the obstetric-physician and a diabetologist. Because of the higher risk of placental insufficiency causing intra-uterine death in the last trimester, 24-hour urine estriol determinations are begun at intervals from the 30th week of gestation. As long as the estriol levels increase progressively, the pregnancy is allowed to continue to near the 37th week of gestation. At that time, amniocentesis for a maturity screen, that is, creatinine level and the ratio of sphingomyelin to lecithin, are determined, and if these are at sufficient levels, the time for delivery can be planned.

Whether to deliver the baby by cesarean section or by induction of labor must be determined by the obstetric-physician, the decision being based on the estimated size of the fetus and whether the baby can tolerate the stress of labor. If induction of labor is chosen, fetal monitoring during labor should be planned.

At birth, the baby is kept warm and is transferred to the infant intensive care unit for observation of its vital functions and blood sugar levels.

Premature Infants

A common admission to the infant intensive care unit is the premature or underweight infant. The admission of such an infant may originate from mothers with preeclampsia or Rh sensitization; premature labor; premature rupture of the bag of waters; premature labor of women with viral infections, pyelonephritis, or septicemia; mothers with "small-for-dates" babies, and mothers of twins.

Some of these conditions can be suspected or recognized by the obstetrician before the onset of labor, and prenatal testing can be decided upon by both obstetric and pediatric physicians. Urine estriol levels can be obtained to survey the fetoplacental function in preeclampsia.

The use of the creatinine level and the ratio of sphingomyelin to lecithin in amniotic fluid for determination of the maturity level is beneficial for the pediatric-physician in anticipating respiratory problems of the small infant.

Ultrasound determinations can help locate the placental site and depict the equivalent size of the fetal skull in "small-for-dates" infants and twin pregnancies.

Infants who are already stressed by maternal diabetes, Rh sensitization, toxemia, prematurity, amnionitis, or intra-uterine malnutrition are likely to become exhausted, anoxic, and acidotic during labor. Fetal monitoring of these infants during labor is a valuable tool in recognizing the problems, allowing delivery prior to the tragedy of intrapartum death.

Prolonged Labor

Prolonged labor or labor without progress is another source of stressed infants at birth. Dysfunctional labor in the primigravida and dystocia

due to cephalopelvic disproportion or malpresentation in either the primigravida or the multigravida are the common causes of prolonged labor. Fetal monitoring during labor is essential in the management of these patients. Infants born of these mothers frequently need immediate resuscitation and close observation of oxygen saturation, glucose levels, and acid-base balance after delivery. If the obstetric-physician anticipates problems for the newborn and has pediatric specialized management available, immediate sequential treatment can be instituted and more babies can be saved.

Conclusion

Although all babies cannot be saved, utilizing present knowledge and techniques and decreasing time delays between obstetric management and pediatric care frequently help. To improve perinatal salvage, the obstetric-physician must anticipate high-risk infants and provide for adequate sequential obstetric-pediatric intensive care.

“Antiacid” action for ulcer patients...

one of the many things you need in an anticholinergic.

Pro-Banthine is provided in several different dosage forms and combinations which will meet virtually any clinical need. It is just as versatile in filling patient needs, among which are:

"Antacid" action—Pro-Banthine® (propantheline bromide) reduces gastric secretory volume and resting total and free acid.

"Sustained" action—Pro-Banthine P.A.® (propantheline bromide) contains 30 mg. of the drug in the form of sustained-release or timed-release beads; on ingestion about half of the drug is released within an hour and the remainder continuously as earlier increments are metabolized.

High-level anticholinergic activity is maintained all day and all night in most patients with only two tablets every eight hours.

"Analgesic" action—Pro-Banthine helps to control the acid-spasm-pain complex.

A **"diagnostic tool"**—Pro-Banthine may be used parenterally to immobilize the duodenum for more revealing roentgenographic appraisal through hypotonic duodenography.

Pro-Banthine is considered adjunctive in total peptic ulcer therapy that may include diet, conventional antacids, bed rest, and other supportive measures.

Vigorous anticholinergic action — Pro-Banthine® Vials, 30 mg., are for intramuscular or intravenous use when prompt and vigorous anticholinergic action is required.

Mild anticholinergic action—Pro-Banthine® Half Strength, 7.5-mg. tablets, for more exact adjustment of maintenance dosage in mild to moderate gastrointestinal disorders.

Indications: Pro-Banthine is effective as adjunctive therapy in the treatment of peptic ulcer. Dosage must be adjusted to the individual.

Contraindications: Glaucoma, obstructive disease of the gastrointestinal tract, obstructive uropathy, intestinal atony, toxic megacolon, hiatal hernia associated with reflux esophagitis, or unstable cardiovascular adjustment in acute hemorrhage.

Warnings: Patients with severe cardiac disease should be given this medication with caution.

Fever and possibly heat stroke may occur due to anhidrosis. In theory a curare-like action may occur, with loss of voluntary muscle control. For such patients prompt and continuing artificial respiration should be applied until the drug effect has been exhausted.

Diarrhea in an ileostomy patient may indicate obstruction, and this possibility should be considered before administering Pro-Banthine.

Precautions: Since varying degrees of urinary hesitancy may be evidenced by elderly males with prostatic hypertrophy, such patients should be advised to micturate at the time of taking the medication.

Overdosage should be avoided in patients severely ill with ulcerative colitis.

Adverse Reactions: Varying degrees of drying of salivary secretions may occur as well as mydriasis and blurred vision. In addition the following adverse reactions have been reported: nervousness, drowsiness, dizziness, insomnia, headache, loss of the sense of taste, nausea, vomiting, constipation, impotence and allergic dermatitis.

Dosage and Administration: The recommended daily dosage for adult oral therapy is one 15-mg. tablet with meals and two at bedtime. Subsequent adjustment to the patient's requirements and tolerance must be made.

Pro-Banthine P.A.—Each tablet of Pro-Banthine P.A. (propantheline bromide) contains 30 mg. of the drug in the form of sustained-release or timed-release beads; on ingestion about half of the drug is released within an hour and the remainder continuously as earlier increments are metabolized. Thus the result is even, high-level anticholinergic activity maintained all day and all night in most patients with only two tablets daily. Some patients may require one tablet every eight hours.

The contraindications and precautions applicable to Pro-Banthine 15 mg. should be observed.

How Supplied: Pro-Banthine is supplied as tablets of 15 and 7.5 mg., as prolonged-acting tablets of 30 mg. and, for parenteral use, as serum-type vials of 30 mg.

The Family Physician

THE COMPARATIVE STUDY of rural and urban physicians in our state and region by faculty of the University of Minnesota Duluth* is to be commended. The identification of variables which clearly differentiate rural and urban family physicians may not be as important as how we implement educational programs to *encourage* and *capture the imagination* of the budding physician. The dire need and necessity to redistribute our physicians appropriately is essential to the health and welfare of our population in the state, region and nation. Applied medical education programs for undergraduate and graduate medical students is essential in developing confidence, poise, deportment, comfortableness and enjoyment in delivering health and disease care to the rural popu-

lace. The Rural Physician Associate Program† at the University of Minnesota Medical School confirms much of what the Duluth faculty are identifying. The program also provides the seed-bed and instrument to allow future physicians the opportunity to experience and understand the nature of life in a small community which the authors believe may be most essential to selection and socialization of medical students for rural practice. Attitudes, skills, and knowledge being equal among our medical students, citizens, and patients—the essential ingredient will be *applying* what we already know about our people and professionals. Exploring *ways to effectively implement* rural medical educational programs for the undifferentiated medical student is essential to continue supplying the rural areas of our state and region with practicing physicians.

Problems of Oral Irradiation

ONE COMPLAINT almost all patients treated for head and neck cancer* have in common is the severe dryness of their mouth. This is something that begins during their treatment course or subsequent to their surgery and continues on almost indefinitely.

With the advent of super-voltage radiation therapy equipment and advances in surgery and anesthesia, a much higher cure rate has been offered to these patients now with head and neck malignancies.

Until recent years, it was an accepted fact that people who were to receive irradiation to the head and neck area must have their teeth extracted prior to irradiation. By close cooperation with the dental sciences and the medical sciences, doctors have now learned that this is not necessary and that many patients can save most of their

teeth provided proper precautions are taken. Thorough evaluation of the teeth prior to treatment, as well as close follow-up of dental care and instruction to the patient on proper dental care after treatment, has made living a little more enjoyable for the fortunate ones who have been cured of their malignancy.

The incidence of osteoradionecrosis has decreased considerably in spite of the fact that much higher doses of irradiation are now given to achieve a higher incidence of cure.

What we do see now is extensive caries formation starting within a few months after completion of irradiation therapy and extending on throughout the lifetime of these patients. Good dental hygiene and adequate dental care have considerably improved the oral health problem of these patients.

Steroid Induced Mediastinal Lipomatosis*

CENTRAL FAT, or centripetal fat deposition, after exposure to excessive endogenous and exogenous corticosteroids is dramatic. It results in some of the well known and classical visible features of Cushing's syndrome, "moon facies," "buffalo hump" and episternal or "dew lap tumor." Less well known, deep seated, and much less common sites are interesting variations: mediastinal widening, epicardial fat pads, pleural and paravertebral tissue thickening, identified as lipomatosis.

The exogenous source of the hormone is an obvious explanation of this manifestation which is apparently reversible when the hormone is discontinued.

The endogenous form is more subtle and chal-

lenging. Spontaneous Cushing's syndrome can be due to bilateral adrenal hyperplasia, resulting in mediastinal fat deposits, but is exceedingly rare. Surgical removal again results in the complete resolution of the process. Even more fascinating, it has been shown that certain non-endocrine tumors are also capable of producing hormones which can stimulate the adrenal cortex. This has been described as an ectopic ACTH syndrome. These tumors form peptides which have corticotropin releasing factor activity. One source of this has been demonstrated in small cell tumors of the lung. It would be important, therefore, to differentiate the more benign lipomatous change produced by Cushing's syndrome with that of this unusual tumor.

Complications of Diverticulitis

BIZARRE PRESENTATION of common disease is a frequently recurring theme in the acute abdomen. A colleague tells the story of a year long contest amongst house officers to see who was most often correct in the diagnosis of the acute abdomen. Naturally, the man who picked appendicitis, regardless of the presenting symptoms or findings, came out ahead. Had the other house officers been more aware of the many faces of diverticulitis and appendicitis, the outcome might have been different. In this issue, Suros and Lec present an

interesting and unusual concurrence of complications of diverticulitis. i.e. Pneumoretroperitoneum, pneumomediastinum and subcutaneous emphysema.*

It would be well to recall that more common but still unusual presentations of diverticulitis include fever of unknown origin, rectal bleeding, mass, passage of gas and feces in the urine or frank peritonitis. Suros and Lee's description nicely documents another of the many possible faces of diverticulitis.

Parkinsonism Disease

WHEN PARKINSONIAN PATIENTS, and families, and their physicians are eagerly awaiting the official release and marketing of the peripheral dopa decarboxylase inhibitors, we are fortunate to have Dr. Tolosa's* review article on The Modern Treatment of Parkinson's Disease.

As of this writing, there is still no release date for the decarboxylase inhibitors. Although they are expected to offer significant improvement to the use of L-Dopa, current reports indicate that there will still be frequent shortcomings in terms of efficacy and side effects to the combined L-Dopa-decarboxylase inhibitor therapy.

In the first wave of enthusiasm over L-Dopa, little attention or credit was given to prior and

other pharmacologic programs for Parkinsonism. It is becoming more apparent that many patients with Parkinsonism need more than L-Dopa for optimal symptomatic relief. It is expected that a similar need will exist with the L-Dopa-decarboxylase inhibitor combination. It is appropriate to review the total pharmacologic approach to Parkinsonism, as Dr. Tolosa has done, and to have our patients on optimal programs while we await the dopa decarboxylase inhibitors.

Although Dr. Tolosa has necessarily introduced us to some of the burgeoning lore and speculation regarding central neuro-transmitter substances and mechanisms, hopefully this will not 'turn off' the average practitioner from the practical side of this review.

Thomas W. Wilson, Jr., M.D.
Minneapolis, Minnesota

Philosophical Musings of a Surgeon

Distorted, eschewed, unreliable figures, expressed by a famous name, are too often repeated as a reliable truth.

Carl O. Rice, M.D.
Editor Emeritus

Sequential Obstetric-Pediatric Intensive Care

THE ARTICLE OF Dr. Sheldon,* emphasizes the importance of intensive care obstetrics and the need for good communication with the pediatrician involved in any case.

The real need is for a cooperative program of care in obstetrics and pediatrics with the help of internal medicine in cases of maternal disease. At the present we are now out of the "quantity" obstetrics era and into the "quality" obstetrics era. It is important that potential high risk obstetric cases be handled by interested, capable obstetricians with delivery scheduled for a hospital which offers intrapartum fetal monitoring and intensive care neonatal nursing.

The article entitled "Antepartum Identification of the Fetus at Risk," by Goodwin, Dunne and Thomas¹ gave a good list of patients with a relative

high risk who should be cared for in a setting where high risk obstetric-neonatal intensive care can be given.

Currently, there is a move to consolidate the high risk obstetrics to certain centers throughout the state in order to achieve better care for these cases.

Rather than be forced to refer certain cases to certain centers, all physicians caring for obstetric patients should select those obstetric patients who are at risk. These patients should be referred to obstetricians who utilize existing hospitals that offer intensive care obstetric and pediatric care.

There is no doubt that teamwork is the key to better results as suggested by Dr. Sheldon.

Peter E. Fehr, M.D.
Minneapolis, Minnesota

Cadaver Organ Retrieval

IN THIS ISSUE Dr. Moberg et al.* perform a valuable service for patients in end stage renal failure, on dialysis, in again calling attention to the pressing need for cadaver organs. Their criteria for brain death are those largely followed on the national scene. In my opinion, the third criterion—"absence of brain stem reflexes" followed by a list of specific reflexes can be simplified simply to absence of all reflexes."

They suggest also the formation of a local liaison team for organ procurement, including internist, nephrologist, surgeon, neurosurgeon, neurologist and paramedical personnel such as hospital chaplain, charge nurse, etc. While this would be ideal, there are many hospitals from which cadaver organs might be procured, where some of the listed specialties are not represented. Furthermore, to assemble such a group on the occasion of cadaver availability would almost certainly be practically unworkable. In addition, the use of a transplant center-based organ procurement team, while ad-

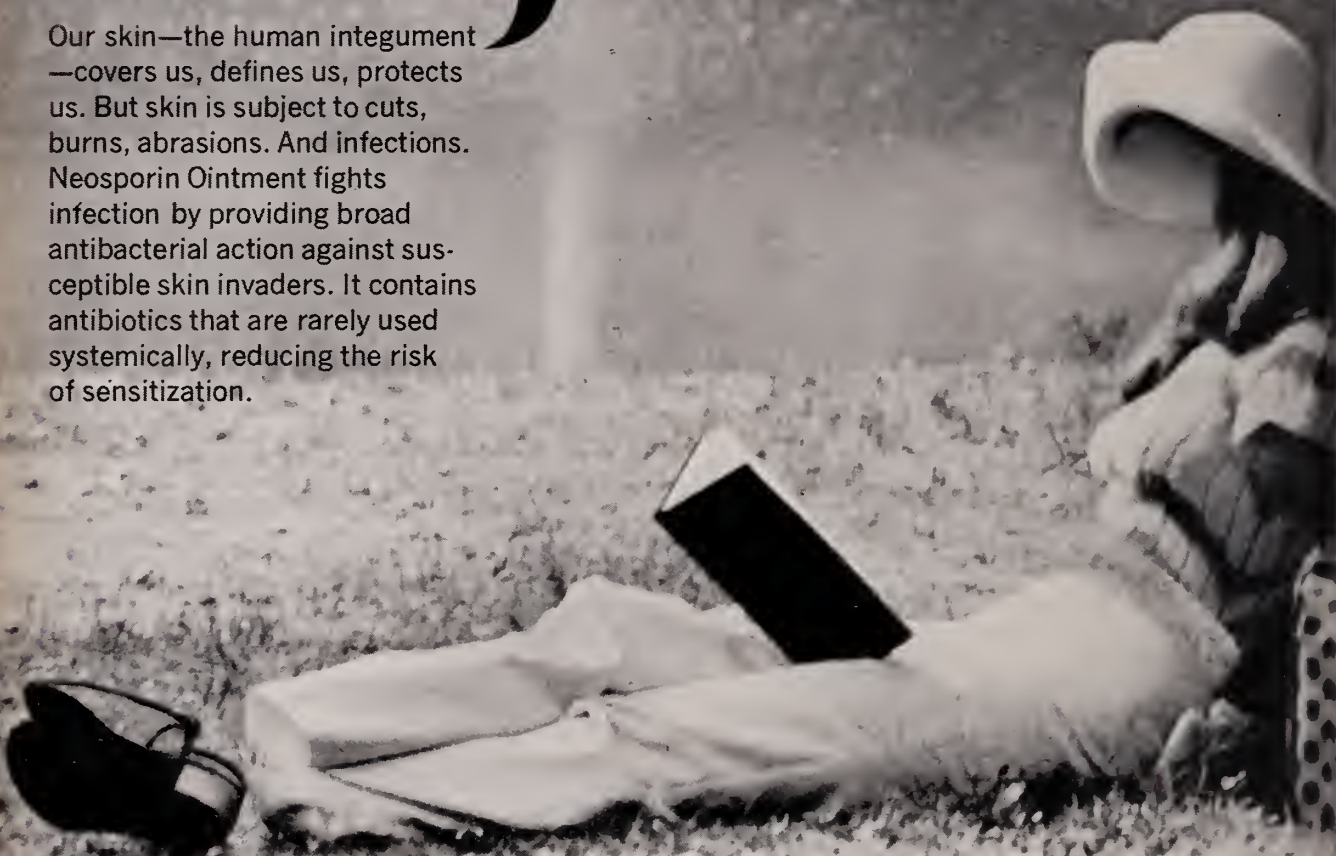

vantageous in some respects, has obvious disadvantages as well.

A reasonable and workable alternative, already in operation in Minnesota as advocated by the Medical Advisory Board of the Upper Midwest Kidney Foundation, is the training of surgeons (general or urological) in the technique of organ retrieval and simple preservation by irrigation with transportation in saline slush to the appropriate transplant center. There are funds currently available for the training of such surgeons (on a one or two day basis) from the Kidney Foundation. A surgeon so trained then may take the initiative at his own local hospital in assuring the use of suitable organs. Certification of brain death by two physicians other than the surgeon is acceptable and practical. It is current practice to reimburse the hospital for all expense involved in organ procurement and to pay the surgeon a reasonable fee for his services in procuring and shipping the organs. This arrangement has already worked successfully where tried.

Integument!

Our skin—the human integument—covers us, defines us, protects us. But skin is subject to cuts, burns, abrasions. And infections. Neosporin Ointment fights infection by providing broad antibacterial action against susceptible skin invaders. It contains antibiotics that are rarely used systemically, reducing the risk of sensitization.

INDICATIONS: *Therapeutically*, used as an adjunct to appropriate systemic therapy for topical infections, primary or secondary, due to susceptible organisms, as in:

- infected burns, skin grafts, surgical incisions, otitis externa
- primary pyodermas (impetigo, ecthyma, sycosis vulgaris, paronychia)
- secondarily infected dermatoses (eczema, herpes, and seborrheic dermatitis)
- traumatic lesions, inflamed or suppurating as a result of bacterial infection.

Prophylactically, the ointment may be used to prevent bacterial contamination in burns, skin grafts, incisions, and other clean lesions. For abrasions, minor cuts and wounds accidentally incurred, its use may prevent the development of infection and permit wound healing.

CONTRAINDICATIONS: Not for use in the external ear canal if the eardrum is perforated. This product is contraindicated in those individuals who have shown hypersensitivity to any of the components.

PRECAUTION: As with other antibiotic preparations, prolonged use may result in overgrowth of nonsusceptible organisms and/or fungi. Appropriate measures should be taken if this occurs. Articles in the current medical literature indicate an increase in the prevalence of persons allergic to neomycin. The possibility of such a reaction should be borne in mind.

Complete literature available on request from Professional Services Dept. PML.

NEOSPORIN[®] Ointment

(POLYMYXIN B-BACITRACIN-NEOMYCIN)

Each gram contains: Aerosporin[®] brand Polymyxin B Sulfate 5,000 units; zinc bacitracin 400 units; neomycin sulfate 5 (equivalent to 3.5 mg. neomycin base); special white petrolatum q.s. In tubes of 1 oz. and ½ oz. and ¼ oz. (approx.) foil pack.

Transfemoral Brachiocephalic Angiography

IN THESE TIMES of radiologic enthusiasm for angiographic visualization of the vascular system, it is comforting to find scientists of repute who examine and report their results dispassionately, logically, and thoroughly. In their manuscript: "The Aortocranial Vessels: The Transfemoral Approach—Analysis of Results and Complications," Talberth and Gold* have rendered a service to the medical community by reminding us that the procedures are not completely innocuous. Good patient care demands that the benefits of our ministrations outweigh the hazards and it behooves us all to examine our practices with that in mind continually.

The present analysis reveals that neurologic complications of transfemoral brachiocephalic angiography are of about the same magnitude as those experienced with direct carotid puncture angiography. In addition, femoral complications were encountered in 8% of the patients including a 2% incidence of thrombosis of the femoral artery which required surgical measures for correction. It is of interest that these latter episodes

occurred in relatively young patients rather than, as might be expected, in the older atherosclerotic age groups. The "hypnotic effects" of catheter angiography (which leads one to persist too long in pursuit of success) touches all of us. The authors point out that many of their less than satisfactory results came after "prolonged studies with considerable manipulation of the catheter."

One can only agree wholeheartedly with the "Indications for Transfemoral Approach" listed in Table 5 as well as the "relative contraindications" detailed in the text. We should take particular note of the fact that only 20.4% of the authors' cerebral angiographic procedures are completed by the femoral route. This figure is low, possibly by a factor of 2 to 3, but it serves to emphasize the continuing need for skill in the techniques of percutaneous puncture of the carotid artery among neuroradiologists.

The lessons in this manuscript are many and the wisdom can be grasped by all who will not ignore it.

The Poet's Blood,

That ever beat in mystic sympathy
With nature's ebb and flow, grew feebler still:
And when two lessening points of light alone
Gleamed through the darkness, the alternate gasp
Of his faint respiration scarce did stir
The stagnate night:—till the minutest ray
Was quenched, the pulse yet lingered in his heart.*

Rural Physicians Associate Program 1971-1972

Crosby, Minnesota

MICHAEL R. SENTA

I REMEMBER how overwhelmed and frightened I was on my first day of the Rural Physicians Associate Program, a Saturday on call, and I remember handling those summer tourist weekends at the end of my year without much trouble at all. Quite a transition took place in my year in Crosby.

Crosby and Dr. Clark Marshall had taken senior medical students for the three summers previous to the Physicians Associate Program, and for that reason they expected too much of me at the beginning of my year, but eventually this was overcome. The first four and a half months were spent in the hospital, as an acting intern, doing histories and physicals on all hospital admissions, writing orders, and on call every third night. In this way I obtained an excellent start in primary care and its responsibilities. I developed a professional relationship with all five doctors which matured over the year so that I could take a night of call usually without bothering the doctor backing me up.

I delivered about 80 babies and assisted on many more. My year was skewed toward surgery. I was involved in the pinning of four hips and some hemorrhoidectomies, herniotomies, vein strippings, appendectomies, D&Cs, T&As, local excisions and some closed orthopedic reductions so I feel confident that I can do those procedures myself. I was first or second assistant on an additional 250-300 surgical procedures. I don't think anyone else in the program had that much surgical exposure. Maybe no one in medical school has ever had that much surgical exposure as a medical student. I learned how to do circumcisions, bone marrow aspirations, lumbar punctures, paracenteses and how to apply casts. I was more than satisfied with the extent of medical skills which I learned while there.

In January I started to work regular hours in the clinic every afternoon. With hospital patients and emergency room returnees as a basis, I gradually developed a full practice, seeing someone every half hour. This soon became every 15 min-

utes, and by early summer I was seeing as many patients as the other doctors, and as quickly. Here too, there were some days I would not have to bother any of the doctors with questions or problems. I had regular patients, and families for up to eight months.

The changes I saw in myself were retrospective and involved my attitude toward the art of medicine. I got irritated and frustrated. I laughed and cried and sometimes raised a little hell. I made medicine fun. It took perhaps six or seven months before I became comfortable and confident.

In reviewing the goals and objectives of the Physicians Associate Program, I think that I fulfilled them. I am proud of Crosby and its five doctors for that reason.

Dr. Walter Sosey was quick to anger, sometimes very slow to give encouragement, but bold, aggressive, and intelligent. Marshall was totally impressive. I worked very hard during the year, and was glad that I had no family which would have demanded time from me. I was happy that I could forego many of my usual outside interests. I feel that only certain personalities could have "survived" a year in Crosby. The program demanded much more time and concentration than a year at Medical School.

Socially I didn't suffer. Walt Sosey, his wife and the surgical scrub nurse and her husband became good friends. They will stay so. I bought a snowmobile. Sosey bought a 750cc Honda so he could keep up with my 750cc B.M.W.

I feel very close to Crosby now. I've been back every three or four weeks since I left. It seems I know every fourth or fifth person on the street downtown. When I left, there were parties and dinners and some embarrassing plaudits. The town did a lot for me as far as teaching me medicine and attitudes concerning people, particularly sick people. It was a satisfying year professionally and emotionally. I think I can be liked and respected and I know I can do the job wherever I wind up, which will very probably be a small town somewhere.

Radioimmunoassay of Circulating Carcinoembryonic Antigen

in Cancer Patients

H. J. SMITH, PH.D.,* P. H. FIGARD, PH.D.,* and M. GÖKCEN, M.D., PH.D.*

CANCER SPECIFIC antigens are of considerable interest because of their importance in the development of immunological methods for the detection, diagnosis, and treatment of cancer. It is only recently that the occurrence of cancer specific

antigens in human cancer has become well established and has led to a surge of interest in the clinical application of tumor immunology.

In 1965 Gold and Freedman¹ reported the identification of a cancer specific antigen in colon cancer. As this antigen was also found to be present in embryonic intestinal tissue it was termed

*Research and Education Division of Health Central Inc., and Life Sciences Foundation, 4101 Golden Valley Road, Minneapolis, Minnesota 55422.

Fig. 1—Radioimmunoassay test for CEA.

Top Row. The small amount of CEA present occupies few antibody sites. Most of the antibody sites are still free to bind ¹²⁵I CEA. The percent of ¹²⁵I CEA bound is therefore large (high level of radioactivity in the precipitate).

Bottom Row. The large amount of CEA present occupies most of the antibody sites. Few of the antibody sites are free to bind the ¹²⁵I CEA. The percent of ¹²⁵I CEA bound is therefore small (low level of radioactivity in the precipitate).

the 'Carcinoembryonic Antigen' (CEA). CEA was purified² and characterized as a protein-polysaccharide complex.³ A radioimmunoassay test for measuring CEA levels in serum was developed by Thomson et al.,⁴ who observed that patients with colon cancer had elevated levels of circulating CEA. Radioimmunoassay tests for CEA are under intensive investigation to determine their potential diagnostic value.⁵⁻⁸

Radioimmunoassay Test for CEA

The principle of the radioimmunoassay test depends upon the competitive binding between the CEA present in the test sample and radioactively labelled CEA (^{125}I CEA) for a limited amount of anti-CEA antibody. The test is illustrated schematically in Figure 1. The absence of CEA in the test sample allows a major fraction of the ^{125}I CEA to bind to the antibody. The presence of CEA in the test sample, however, inhibits the binding of ^{125}I CEA by competing for the available antibody sites. With increasing amounts of CEA present in the test sample there is a progressive decrease in the amount of ^{125}I CEA bound. By using known standardized amounts of CEA an inhibition curve for the standards can be prepared (Figure 2). The CEA content of an unknown sample can now be estimated by determining the percent inhibition given by the sample and comparing it to the standard inhibition curve. The results are expressed in nanograms of CEA per ml of serum or plasma (ng./ml. CEA).

Fig. 2—Radioimmunoassay test for CEA. Standard Inhibition Curve.

We have developed a sensitive radioimmunoassay test for CEA⁹ in our laboratories using highly purified CEA and ¹²⁵I CEA preparations, and monospecific rabbit anti-CEA antiserum. The sensitivity of the test allows us to measure the CEA content in 1 ml. samples of either serum or plasma, within a working range of 0.5 to 32 ng./ml. CEA. We are using this radioimmunoassay procedure to investigate the level of circulating CEA in patients with a variety of cancers, and in screening normal individuals.

Results

The results we have obtained to date of CEA levels in healthy persons and in patients with different cancers are given in Table 1.

TABLE 1
Circulating CEA Levels in Patients with Different
Cancers. The Normal Range was determined for
33 Healthy Persons.

Melan Cancer	Malignant Melanoma	Breast Cancer	Ovarian Cancer	Cancer Cecum	Chronic Myelogenous Leukemia	Multifocal Myeloma
• • • • •	• • • • • • •	•	•	•	•	• •
• • •	• • •	• •				

Normal Individuals

We observed that 33 normal healthy persons had circulating CEA levels that ranged from 0 to 1.3 ng./ml. CEA. We consider CEA levels above 1.3 ng./ml. to be abnormal. The 0 to 1.3 ng./ml. CEA range reported here is comparable to the 0 to 2.5 ng./ml. range observed by others,⁴⁻⁸ as the CEA preparations used in our assay are approximately twice as active antigenically as other CEA preparations.

Patients with Colon Cancer

Ten patients with colon cancer were found to show a range of circulating CEA levels from 0.3 to 35 ng./ml. CEA, with eight patients having abnormal CEA levels. All eight patients with elevated CEA levels also had known metastatic cancer, while the two patients with low levels after surgery were apparently free of tumor. Our observations are in accord with those reported by

Thomson et al.,⁴ and Dhar et al.⁸

CEA in Colonic Cancer

Case 1. A 50-year-old man underwent surgery for cancer of the colon. There were extensive abdominal metastases with infiltration of the kidneys and liver. The preoperative serum sample was 24 ng./ml. CEA. The postoperative serum sample taken three months after surgery showed the same level.

Case 2. A 57-year-old man with cancer of the colon had a partial gastrectomy and a resection of his tumor. Active immunization of the patient to his tumor was initiated for a period of six months following surgery. Two years later there is no obvious tumor recurrence and the CEA level in the patient's serum is 1.0 ng./ml.

Patients with Malignant Melanoma

The radioimmunoassay tests for CEA in patients with malignant melanoma showed a range of circulating CEA levels from 0 to 10 ng./ml. CEA. Eleven of the 10 melanoma patients had levels above normal. We are unable to find any reports in the literature of elevated CEA levels in malignant melanoma. Six melanoma patients with abnormal CEA levels also had known metastases. A patient with localized tumor that was surgically removed showed a postoperative elevated CEA. In contrast, three patients with low CEA were apparently free of tumor since surgery several years previously.

CEA in Malignant Melanoma

Case 1. A 66-year-old man had a malignant melanoma resected from the left shoulder. Five years later a recurrent melanoma was removed, and a radical axillary dissection performed. Active immunization of the patient to his tumor was then initiated for a period of 1.5 years following surgery. Two years later the patient presented with recurrent tumor and surgery revealed extensive abdominal metastases. Serum samples taken at various intervals during the course of the disease showed a persistent elevated CEA with a current level of 10 ng./ml.

Case 2. A 46-year-old woman had surgical removal of malignant melanoma of the left leg. One year later a recurrent cancer in the same area was removed with dissection of the left groin area. The following year she was again operated upon for tumor recurrence in the same area. Active immunization of the patient to her neoplasm was then initiated for a period of two years at which time the patient's CEA level was 0 ng./ml.

Case 3. A 52-year-old male had removal of a malignant melanoma of the left forearm. The postoperative serum sample taken one month after surgery showed an elevated CEA level of 4.5 ng./ml.

CEA in Miscellaneous Cancers

Preliminary results showed that patients with malignancy of the breast, ovary, cecum or with chronic myelogenous leukemia may also have elevated CEA. The results are in accord with the accumulating reports that patients with different cancers may have elevated CEA levels. Lo Gerfo

et al.⁵ and Reynoso et al.⁷ have reported increased CEA in patients with carcinoma of the gastrointestinal tract, breast, or of the genitourinary system. The various reports of the incidence of abnormal CEA levels in patients with different cancers are collated in Table 2,

Localized breast cancer

Misc. cancers

Discussion

It can be seen that in addition to patients with colon carcinoma, elevated CEA levels may also be found in patients with cancers at other sites. The CEA test cannot by itself be considered to be diagnostic for colon cancer, but may be of some diagnostic value when used in conjunction with other clinical tests.

Circulating CEA levels have been found to be useful in the staging of malignant tumors. Dhar et al.⁸ and Kleinman and Turner⁶ have reported that colon cancer patients with localized tumors had a low incidence of abnormal CEA levels while all patients with metastatic cancer had high levels. The results reported here are in agreement. Our observation that melanoma patients with localized tumor usually had normal CEA while those with metastases had elevated levels, suggests that the CEA test could also be used in staging of malignant melanoma. A similar suggestion for staging of breast cancer has been put forward by Reynoso et al.⁷

The measurement of CEA before and after treatment has also been found to be of value in

determining the success of therapy, and in monitoring the subsequent course of the disease. Thomson et al.⁴ and Dhar et al.⁸ have observed that CEA levels in colon cancer patients would often fall after surgical removal of the tumor. A persistent high CEA level postoperatively may indicate the presence of residual tumor.⁸ A fall in CEA followed by a subsequent rise may indicate tumor regrowth.⁸ Reynoso et al.⁷ found that children with neuroblastoma had elevated CEA levels, but that these fell to within the normal range when the cancer was in remission.

Patients with certain non-malignant diseases may also have elevated CEA levels. Lo Gerfo et

al.⁵ have reported increased CEA levels in 32% of patients with ulcerative colitis, and in 11% of patients with pulmonary disease. Moore et al.¹ found 45% alcoholic patients with liver disease had raised CEA levels. In most instances however it is possible to determine the conditions that affect the CEA level.

The examples discussed in this report illustrate the value of determination of CEA levels in the detection, treatment, and prognosis of cancer.

Acknowledgments

We wish to thank Dr. F. Ankner and Dr. C. Everhart for supplying tissue specimens and serum samples, and P. J. O'Neill for her helpful criticism of this paper.

Metastatic Testicular Neoplasm to the Kidney

WILLIAM DeWOLF, M.D.* and ELWIN E. FRALEY, M.D.†

NEOPLASMS METASTATIC to the kidney are not uncommon and are found in 8% of patient's dying from malignant disease.¹ It is unusual for a metastases to present as a solitary renal mass, and to cause urinary tract symptoms. This is a case report of a patient with a mixed testicular tumor, metastatic to the kidney presenting with hematuria.

Case Report

A 29-year-old male was well until eight months prior to admission when he noticed that his right testicle was hard.

*Resident in Urology, University of Minnesota, Minneapolis.
†Professor and Chairman, Division of Urology, Department of Surgery, University of Minnesota, Minneapolis.

Figure—Microscopic section of kidney demonstrating metastatic foci of embryonal cell carcinoma and choriocarcinoma.

Subsequent inguinal orchiectomy showed an embryonal testicular carcinoma with elements of seminoma and choriocarcinoma. Soon thereafter the patient had metastases in the lungs and abdominal lymph nodes, and was treated with radiotherapy, vinblastine sulfate (Velban), bleomycin, cyclophosphamide (Cytosan) and dexamethasone (Decadron) at various intervals. Three months later the patient was readmitted for evaluation of gross hematuria. Hematologic studies showed a platelet count of 45,000/mm.² Intravenous pyelogram showed a mass in the lower pole of the left kidney. After a platelet infusion the bleeding stopped. Several weeks later the patient died. Pathological examination of the left kidney revealed several foci of metastatic tumor, the largest 3 cm in diameter, hemorrhagic and composed of chorionic and embryonal elements (Figure).

Discussion

Metastatic disease to the kidney is more than twice as common as primary lesions.² The kidney ranks fifth as a site of metastases after lung, liver, bones and adrenals.³ Primary tumors of the breast and lung are the most common tumors to metastasize to the kidney.⁴ While testicular neoplasms have been shown to produce microscopic foci of metastases in the kidney, they rarely become massive causing hematuria. This is probably because the patient does not live long enough for symptoms to develop.

Treatment for such a problem is symptomatic, and surgery is reserved for uncontrolled sepsis, pain or bleeding.

Recommendations[†] on Combination Live Virus Vaccines

American Academy of Pediatrics

Committee on Infectious Diseases

In the September 15, 1971 AAP Newsletter sent to Academy members, the Committee on Infectious Diseases of the American Academy of Pediatrics stated its recommendations on the use of combination live virus vaccines. After a careful review of available data, the committee concluded that:

- "This information indicates that the products are both safe and effective when used as directed."
- The vaccine "...can, therefore, be recommended with the obvious advantages of reduction in the number of injections for any given child and a concomitant decrease in the required visits to a physician's office or clinic."

[†]For complete text of both recommendations see your MSD representative or write to Professional Service Dept., Merck Sharp & Dohme, West Point, Pa. 19486.

United States Public Health Service

Advisory Committee on Immunization Practices

In the April 24, 1971 issue of *Morbidity and Mortality Weekly Report*, the Advisory Committee on Immunization Practices of the United States Public Health Service presented recommendations on the use of combination live virus vaccines. The committee stated that:

- "Data indicate that antibody response to each component of these combination vaccines is comparable with antibody response to the individual vaccines given separately."
- "There is no evidence that adverse reactions to the combination products occur more frequently or are more severe than known reactions to the individual vaccines (see pertinent ACIP recommendations)."
- "The obvious convenience of giving already selected antigens in combined form should encourage consideration of using these products when appropriate."

M-M-R^{*}

(MEASLES, MUMPS AND RUBELLA VIRUS VACCINE, LIVE | MSD)

Single-dose vials

M-M-R, given in a single injection, fits easily into your routine immunization program for well babies. Given at age 12 months, M-M-R provides for vaccination early in life against measles, mumps, and rubella.

MSD suggested immunization schedule for well babies	
Age	Vaccine(s)
2 months	DPT (diphtheria-pertussis-tetanus) Oral poliomyelitis vaccine (triple)
3 months	DPT ¹
4 months	DPT Oral poliomyelitis vaccine (triple)
6 months	Oral poliomyelitis vaccine (triple)
12 MONTHS	M-M-R (MEASLES, MUMPS AND RUBELLA VIRUS VACCINE, LIVE, MSD)

1. This vaccination may be given at 3 months, 5 months, or at 6 months, depending on your preference or on the condition of the child.
Since vaccination with a live virus vaccine may depress the results of a tuberculin test for four weeks or longer, the test and the vaccine should not be given during the same office visit.

^{*}Trademark of Merck & Co., Inc.

For a brief summary of prescribing information, please see following page.

M-M-R

(MEASLES, MUMPS AND RUBELLA VIRUS VACCINE, LIVE | MSD)

Single-dose vials

No untoward reactions peculiar to the combination vaccine (M-M-R) have been reported.

Moderate fever (101-102.9 F) occurs occasionally. High fever (over 103 F) occurs less commonly. On rare occasions, children who develop fever may exhibit febrile convulsions. Rash (usually minimal and without generalized distribution) may occur infrequently.

Since clinical experience with measles, mumps, and rubella virus vaccines given individually indicates that very rarely encephalitis and other nervous system reactions have occurred, such reactions may also occur with M-M-R. A cause and effect relationship, however,

has not been established.

Excretion of the live attenuated rubella virus from the throat has occurred in the majority of susceptible individuals administered the rubella vaccine. There is no definitive evidence to indicate that such virus is contagious to susceptible persons who are in contact with the vaccinated individuals. Consequently, transmission, while accepted as a theoretical possibility, has not been regarded as a significant risk.

Must not be given to women who are pregnant or who might become pregnant within three months following vaccination.

Contraindications: Pregnancy or possibility of pregnancy within three months following vaccination; infants less than one year old; sensitivity to chicken or duck, chicken or duck eggs or feathers, or neomycin; any febrile respiratory illness or other active febrile infection; active untreated tuberculosis; therapy with ACTH, corticosteroids, irradiation, alkylating agents, or antimetabolites; blood dyscrasias, leukemia, lymphomas of any type, or other malignant neoplasms affecting the bone marrow or lymphatic systems; gamma globulin deficiency, i.e., agammaglobulinemia, hypogammaglobulinemia, and dysgammaglobulinemia.

Precautions: Administer subcutaneously; do not give intravenously. Epinephrine should be available for immediate use should an anaphylactoid reaction occur. Should not be given less than one month before or after immunization with other live virus vaccines; vaccination should be deferred for at least six weeks following blood transfusions or administration of more than 0.02 cc immune serum globulin (human) per pound of body weight, or human plasma.

Due caution should be employed in children with a history of febrile convulsions, cerebral injury, or any other condition in which stress due to fever should be avoided. The physician should be alert to the temperature elevation which may occur after vaccination.

Excretion of the live attenuated rubella virus from the throat has occurred in the majority of susceptible individuals administered the rubella vaccine. There is no definitive evidence to indicate that such virus is contagious to susceptible persons who are in contact with the vaccinated individuals. Consequently, transmission, while accepted as a theoretical possibility, has not been regarded as a significant risk.

Attenuated live virus measles and mumps vaccines, given separately, may temporarily depress tuberculin skin sensitivity; therefore, if a tuberculin test is to be done, it should be scheduled before vaccination, to avoid the possibility of a false negative response.

Before reconstitution, refrigerate vaccine at 2-8 C (35.6-46.4 F) and protect from light. Use only diluent supplied to reconstitute vaccine. If not used immediately, return reconstituted vaccine to refrigerator at 2-8 C (35.6-46.4 F), and discard after eight hours.

Adverse Reactions: Fever, rash; mild local reactions such as erythema, induration, tenderness, regional lymphadenopathy; parotitis; thrombocytopenia or purpura; allergic reactions such as urticaria; arthritis, arthralgia, and polyneuritis.

Occasionally, moderate fever (101-102.9 F); less commonly, high fever (above 103 F); rarely, febrile convulsions.

Encephalitis and other nervous system reactions that have occurred very rarely with the individual vaccine may also occur with the combined vaccine.

Transient arthritis, arthralgia, and polyneuritis are features of natural rubella and vary in frequency and severity with age and sex, being greatest in adult females and least in prepubertal children. Such reactions have been reported with live attenuated rubella virus vaccines. Symptoms relating to joints (pain, swelling, stiffness, etc.) and to peripheral nerves (pain, numbness, tingling, etc.) occurring within approximately two months after immunization should be considered as possibly vaccine related. Symptoms have generally been mild and of no more than three day duration. The incidence in prepubertal children would appear to be less than 1% for reactions that would interfere with normal activity or necessitate medical attention.

How Supplied: Single-dose vials of lyophilized vaccine, containing when reconstituted not less than 1,000 TCID₅₀ (tissue culture infectious doses) of measles virus vaccine, live, attenuated, 5,000 TCID₅₀ of mumps virus vaccine, live, and 1,000 TCID₅₀ of rubella virus vaccine, live, expressed in terms of the assigned titer of the NIH Reference Measles, Mumps, and Rubella Viruses, and approximately 25 mcg neomycin with a disposable syringe containing diluent and fitted with a 25-gauge, 5/8" needle. Also in boxes of 10 single dose vials nested in a pop-out tray with a separate box of 10 diluent-containing syringes.

Fracture Conference

Puncture Wounds of the Foot

HAMLET A. PETERSON, M.D.*, HUBERT A. TRESSLER, M.D.†,
ALLEN G. LANG, M.D.† and EINER W. JOHNSON, JR., M.D.*

Dr. Hamlet A. Peterson:

This conference concerns puncture wounds of the foot, which occur frequently, particularly during the summer months. The patient usually is a child who comes to the emergency room with a puncture hole in the foot after having stepped on a nail or some other pointed object. Dr. Petty, what is your approach in this situation?

Dr. Roy W. Petty:

I would get the foot clean by having the patient soak it for 15 minutes and administer tetanus prophylaxis with either active immunization or a booster.

Dr. Peterson:

Would you have an Xray taken?

Dr. Petty:

Yes, if the patient had stepped on a rather large nail. But if the nail was small, and there was just a little prick in the skin, then I wouldn't.

Dr. Peterson:

The approach that Dr. Petty outlined is a rather standard one in treating a puncture wound of the foot. Some situations require more aggressive approaches, and to illustrate this, we are going to describe three cases.

Case 1

Dr. Hubert A. Tressler:

The first patient is a 13-year-old boy who sustained a puncture wound of the right foot on Aug. 20, 1971. A nail pierced the sole of his tennis shoe, through the foot,

Fig. 1 (Case 1)—(A) and (B). Osteomyelitis of right third toe nine months after puncture wound. (C) Right proximal phalanx of third toe after saucerization. (D) Proximal phalanx of right third toe eight months after saucerization.

and exited on the dorsum. The wound was in the plantar surface on the lateral aspect of the third proximal phalanx. The patient was treated initially with penicillin by his physician father. Five days later, the patient was sent to the emergency room for a tetanus booster. The wounds had closed, and no Xray was taken. The wound healed, and the patient was active and asymptomatic all winter. On May 24, 1972, nine months after injury, he returned complaining of swelling and pain in the third toe on his right foot. Dr. Monkman, would you comment on these Xrays (Figure 1A and B)?

Dr. George R. Monkman:

There is evidence of sclerosis at the base of the third proximal phalanx.

Dr. Peterson:

Would you comment on the epiphyseal growth plate?

Dr. Monkman:

The plate is apparently involved. It does not appear to be long enough.

Dr. Peterson:

Since it is now nine months after injury, what treatment should be carried out?

Dr. Monkman:

I think that the area should be opened and debrided and cultures taken.

Dr. Peterson:

What type of an approach would you use?

Dr. Monkman:

Possibly, a dorsal approach in one of the web spaces.

Dr. Tressler:

Ten months after injury, saucerization of the proximal phalanx of the right third toe was performed (Figure 1C). Gross pus was not encountered in the soft dead bone. Cultures were taken, and these revealed *Pseudomonas aeruginosa* and *Staphylococcus epidermidis*. The patient was given gentamicin, as dictated by sensitivity studies.

Dr. Peterson:

The complete center of the phalanx was removed, but the epiphyseal growth plate was not further damaged.

Dr. Monkman:

What was the dose and duration of gentamicin therapy?

Dr. Tressler:

Gentamicin was given intravenously in 40-mg doses, three times a day for nine days, and methicillin was given intravenously in 500-mg doses, four times a day for 12 days.

Do you think that this therapy was long enough?

Dr. Monkman:

Well, probably not. But the duration should depend on subsequent cultures.

Dr. Tressler:

The feeling was that the thorough surgical debridement was the primary treatment and that the use of antibiotics was secondary. The wound was too small to irrigate. Eight months after saucerization, the patient was asymptomatic (Figure 1D).

Dr. Monkman:

There is still some evidence of sclerosis in the proximal phalanx, and the epiphyseal plate is still abnormal. The cavity that we saw earlier has apparently healed.

Dr. Peterson:

The small, round lytic areas that were surrounded by sclerosis are no longer present (compare Figure 1A and B with D). There is a shortening of the phalanx and some angulation. There was more damage of the epiphysis on one side than on the other. Do you think that this injury is going to cause a later problem? The boy is still growing and is 13 years old now. He was 11 years old at the time of the injury.

Dr. Monkman:

This depends on how much growth he has left.

Dr. Peterson:

Dr. Linscheid, do you think that the injury would cause any difficulty?

Dr. Ronald L. Linscheid:

I suspect that he will tend to nestle down on the second toe.

Dr. Peterson:

Is any additional treatment necessary now?

Dr. Anthony J. Bianco, Jr.:

I wonder whether the joint might be involved later. Degenerative changes of the joint may occur but I doubt whether the position of the toe will change.

Dr. Peterson:

No more treatment is contemplated at the present time.

Case 2

Dr. Tressler:

The second patient is a 12-year-old boy who sustained a nail puncture wound on the plantar surface of the left foot eight months previously. The only initial treatment was a tetanus booster. The wound drained pus for three weeks and closed spontaneously. No cultures were taken. The wound has drained on two more occasions. The patient has soaked his foot and has taken antibiotics (types unknown). His main complaint on the first visit

PUNCTURE WOUNDS OF THE FOOT

was swelling and pain over the volar lateral aspect of the foot. The leukocyte count was 9,200/cu mm, and the sedimentation rate was 36 mm in one hour. Dr. Barron, will you comment on the Xrays (Figures 2A and B)?

Dr. Stephen E. Barron:

There is evidence of sclerosis on one of the tarsal bones. The boy probably has a low-grade osteomyelitis.

Dr. Peterson:

The sclerosis of the cuboid corresponds with the area of the puncture wound and the recurrent drainage.

Dr. Tressler:

What would you suggest be done now?

Dr. Barron:

I think I would get a culture of the drainage to see what you are dealing with. Cultures for fungus as well as bacteria should be taken.

Dr. Peterson:

It was not draining at that time.

Dr. Barron:

Then I think that one would have to go in and debride the apparent area of infection, and possibly close it over secondarily.

Dr. Tressler:

Surgical debridement was performed, and the wound was packed open for two days. Two days later, the cultures showed no growth. The wound was again cultured, further debrided, and closed with the boy under general anesthesia. The cultures subsequently grew *P. aeruginosa*, *Escherichia coli*, *Streptococcus*, *Fusobacterium necrophorum*, *Peptococcus*, and *Propionibacterium*. No antibiotics were given. The wound healed without incident. Six months later, the foot was asymptomatic and the sedimentation rate was 23 mm in one hour.

Fig. 2 (Case 2)—(A) and (B) Osteomyelitis of left cuboid eight months after puncture wound. (C) and (D), Left cuboid two and a half years after saucerization. Patient was asymptomatic.

The patient was last seen two and a half years after surgery, and he continued to be normally active and asymptomatic (Figures 2C and D).

Dr. Peterson:

At surgery, no pus or foreign material was found, but the cultures later were positive. The wound was packed open for two days and then was closed. No antibiotics were given at anytime. The boy has remained asymptomatic for two and a half years after this procedure, and looking at the Xray, I suppose that one would be hard pressed to state whether he is really over his problem or not. As long as he remains asymptomatic, I feel that no further treatment is indicated, although I don't think you could say with 100% assurance that there won't be a problem in the future.

Dr. Joe W. Crow:

Why wasn't he treated with antibiotics?

Dr. Peterson:

No antibiotics were given initially because no pus was encountered and the initial cultures were negative. Although the initial cultures subsequently grew organisms, the wound was closed by that time. In essence, it was felt that the surgical debridement, performed twice, was sufficient.

Case 3

Dr. Tressler:

The third patient was 17 years old when she was first seen in orthopedic consultation in July 1969. A nail had pierced her left foot in 1963, when she was 12 years old. Initial treatment consisted of a tetanus booster. Two years later (1965), incision and drainage of the third metatarsal were performed elsewhere. Cultures revealed *Proteus* organisms, and antibiotics were given. The wound required dressing changes and soaks, and healed three months later. Intermittent pain and swelling did not limit her activities, but these gradually became worse during the subsequent four years.

When first seen at our clinic in 1969, the girl had mild swelling and tenderness over the second and third metatarsals. The roentgenogram (Figure 3A) showed

evidence of sclerosis and a deformity of the third metatarsal shaft, with some increased thickness of the second metatarsal shaft cortices.

Dr. Peterson:

Six years after injury, the patient had recurrent pain and swelling, but this was not severe. She limped occasionally. Dr. Rab, would you comment please?

Dr. George T. Rab:

The entire shaft of the third metatarsal looks a little sclerotic.

Dr. Peterson:

Some days the foot looked completely normal whereas other days it was a bit swollen and tender over the third metatarsal, nothing more.

Dr. Rab:

I think the area should be explored surgically.

Dr. Tressler:

No treatment was advised. In the summer of 1971, which was eight years after her injury, she returned to our clinic. At that time, she had pain and swelling of the foot but no fever or drainage. She had mild swelling on the dorsum of the foot, with tenderness over the third metatarsal. Her sedimentation rate was 28 mm in one hour. The leukocyte count was 4,900/cu mm, with a normal differential count. Eight years after injury, she now has intermittent pain and swelling that have increased during the past several months.

Dr. Peterson:

The Xrays have shown no changes except for evidence of increased sclerosis of the second metatarsal shaft, with narrowing of its intramedullary canal. Dr. Rab, do you think a stress fracture could produce all of these changes?

Dr. Rab:

No.

Dr. Tressler:

Between April and October 1971, successive

Fig. 3 (Case 3)—(A) Osteomyelitis of left second and third metatarsals six years after nail puncture wound. (B) Left second and third metatarsals after saucerization. (C) Left second and third metatarsals one and a half years after saucerization. Pain and swelling of foot are present.

sedimentation rates were 28, 30, 46, 54, 65, and 66 mm in one hour. At surgery the second and third metatarsals were saucerized, and cultures were taken (Figure 3B). Two days later, suction-irrigation was begun.

Dr. Peterson:

The third metatarsal was fractured during removal of the dorsal half of the bone. Saucerization of both metatarsals was carried distally after this operative Xray was taken. The wound was packed open for a couple of days until the results of cultures were reported.

Dr. Tressler:

Cultures from the third metatarsal grew *P. aeruginosa* and from the second metatarsal *S. epidermidis* and *Streptococcus* of the viridans group.

Dr. Peterson:

Isn't it strange that different organisms were cultured from each metatarsal? It makes one wonder if there was a contaminant. A separate irrigation system was instituted for each metatarsal. Even though the tubes were tiny, they irrigated well for 14 days. The third metatarsal was irrigated with gentamicin, and the second with normal saline and tyloxapol (Alevaire). Penicillin was given intravenously in a dose of 20 million units every 24 hours.

Dr. Tressler:

The wounds healed per primum. The girl continued to have intermittent swelling and pain. Fourteen months after operation (nine and a half years after injury), the Xrays showed evidence of sclerosis of both metatarsal heads.

Dr. Rab:

If this patient had asked you before surgery what the chances of success would be, what would you have told her?

Dr. Peterson:

I think the standard way to approach this question is to point out that historically once a patient has osteomyelitis he will always have osteomyelitis. At the present time, however, with better diagnosis and surgical management, supplemented with antibiotics, there is a reasonable chance that osteomyelitis can be cured. With this approach the patient is aware that cure is not possible in every case of chronic osteomyelitis.

Dr. Rab:

I asked this question because of a problem that has arisen in a few cases. The patient was told that he has a 70 to 80% chance of cure, and then

the physician working in the infectious disease area tells the patient that the chance of cure is 40%.

Dr. Peterson:

Once you start playing the game of percentages, you are in trouble. Each case is different, each with a specific bone and a specific infecting organism. Host resistance and organism virulence cannot be equated.

Dr. Mark B. Coventry:

It is very wise to avoid percentages in anything. When you start talking about percentages in something as indefinite as osteomyelitis, the patient tends to remember only some specifics. It is much wiser to do as Dr. Peterson says, namely, tell the patient that we may be able to give him relief and that we will try. I wouldn't go further than that. What is her state of health now? Is she well or not?

Dr. Tressler:

She has improved somewhat, but continues to have intermittent pain similar to the discomfort with which she presented in 1969, prior to surgery.

Dr. Coventry:

Do you think it is possible to properly saucerize, if that is the term, two tiny metatarsals like this? In the past, I have faced this by simply excising everything, knowing that I can't be sure which is viable bone or not.

Dr. Peterson:

Removal of the dorsal half of this small dense sclerotic bone was technically difficult. Removal of an adequate amount of bone invited fracture, but it was worth a try at that point. She has been seen frequently, and her sedimentation rate went from 20 to 65 mm in one hour during the two years from 1969 to 1971. After surgery, her sedimentation rate gradually decreased to 20. However, two months ago, it was up to 65 again. She also has recurrent symptoms. Some weeks she is fine. Then her limp will return, with swelling and tenderness over the dorsum of the foot. I don't think another course of antibiotics is indicated at this time. Excision of both metatarsal shafts as mentioned by Dr. Coventry appears to be the logical recommendation.

Dr. Bianco:

In line with what Dr. Coventry said, I have treated a boy who lost two metatarsal shafts in a snowmobile accident, and the defects were big enough so that the dorsum of the foot had to be skin grafted. He has had no significant disability at all.

Dr. Peterson:

The girl in the present case has questioned me closely about such an excision. What is her foot going to be like if these two metatarsal shafts are removed? I haven't been able to promise that she is going to be much better. How do you feel about this, Dr. Coventry?

Dr. Coventry:

Well, I think that she is not going to have a normal foot. Of course, you don't want to make her foot any worse, and you would like to maintain her toe length. But she will have a reasonably normal foot even if the second and third toes do shorten. She won't like the cosmetics, but I don't suppose she likes the recurrent pain and swelling, so she could trade one for another.

Dr. Peterson:

This is essentially what the patient has been told. She has been unwilling to go ahead with any more surgery at this time.

Dr. Einer W. Johnson, Jr.:

In your experience, Dr. Coventry, if you leave the periosteum, do you get any recovery or return of the shaft?

Dr. Coventry:

Oh, yes. In children I think you get a full return, as Dr. Peterson will testify, but I am not so sure that the metatarsal shaft will regenerate in adults.

Dr. Peterson:

This girl is now in her early twenties, and I would not count on it.

Dr. Coventry:

I wouldn't either.

Dr. Peterson:

The literature concerning puncture wounds is sparse. Dr. Lang has surveyed the literature and will give us a résumé.

Comment and Literature Review

Dr. Allen G. Lang:

Because of the severe complications from such a common injury as those presented in this fracture conference, I tried to find whether similar problems have been reported, how they had been handled, and whether any large series had been evaluated to determine the incidence of these complications. Actually, very little is available. One article consisted of a single case report of typhoid osteomyelitis of the os calcis after a puncture wound.¹

Two more pertinent articles included case re-

ports on *Pseudomonas* osteomyelitis. All patients were children, and all had prolonged hospitalizations and aggressive parenteral antibiotic therapy with surgical debridement, and all had some residual deformity. In 1968, Johanson² described 11 patients with *Pseudomonas* osteomyelitis after puncture wounds of the foot. In these patients, definitive diagnosis was delayed an average of three weeks. Certain characteristics were present in all 11. All patients received prophylactic antibiotics, tetanus toxoid, and local wound care consisting of nonsurgical cleansing, and all were advised to soak, rest, and elevate the foot. All patients improved during the 48 to 72 hours after injury and all then had increasing pain, discomfort, and swelling in the foot later. However, none of the patients was systemically ill, and only minimally elevated leukocyte counts and sedimentation rates were noted. After sufficient lapse, x-ray changes were noted; these consisted of generalized osteoporosis with demineralization especially marked at the infection site. In all 11 patients, the sites were either aspirated or surgically opened. All cultures grew *P. aeruginosa*, but the Gram stain in 10 of the 11 cases was negative. In three of the cases, previous cultures of the puncture wound had grown *S. aureus*. The author pointed out that the primary focus of infection in all of these patients seemed to be cartilaginous tissue, either articular cartilage or the cartilaginous growth plate. All 11 patients had significant sequelae: joint degeneration or premature closure of growth plates or both. Johanson recommended that puncture wounds in noncartilaginous areas be treated with simple debridement of superficial tissues. For cartilaginous area, he stated that "empiric reasoning suggests that debridement, irrigation, and closure over irrigation tubes are appropriate."

In 1971, three more patients with *Pseudomonas* osteomyelitis were described.³ Two of these presented the typical clinical findings as previously described, the symptoms beginning three to four days after injury. The third presented with a swollen painful foot 19 days after injury. All three were treated with surgical debridement and intravenously administered antibiotics, and all three had good clinical results.

The three cases presented herein and the cases reported in the literature were all from medical centers with preselected populations, and no attempt was made to evaluate the incidence of

these complications. In 1962, Houston et al.⁴ reviewed a series of 2,583 patients with puncture wounds who were seen during a seven-year period in various institutions in New Orleans. More than 90% of the injuries involved the soles of the feet. Two hundred eighty (11%) had late infections; these were mostly early cellulitis, which cleared overnight after debridement. This left 2,303 patients who had no infection when first seen. Of these, 51 patients (2%) developed wound infection, of which one patient had osteomyelitis.

These results were obtained with the following standardized treatment regimen. The wounds were cleansed with hexachlorophene and water, and the epidermal edges were excised using an ordinary cuticle clipper, thus visualizing the wound for irrigation and removal of gross contaminants. A dry sterile dressing was then applied, and the patient was instructed to spread the wound open and soak it several times a day for a few days and to return only if signs of inflammation developed. For wounds that were deeper or bled significantly, a one-quarter inch iodoform gauze sock, which was soaked in erythromycin, was used for one to two days. All patients received tetanus immunizations, and 20% of those seen with fresh injuries received antibiotics, either as prophylaxis or later as treatment for a subsequent infection. Eighty percent of the patients who were initially seen with established infections received antibiotics. Of the 51 patients who were seen with fresh injuries and who developed infection later, no data were provided as to whether or not they received antibiotics prophylactically.

Summary and Closing Comments

The incidence of infection in patients with puncture wounds who receive good primary care is low, and the incidence of osteomyelitis is extremely low. However, if a patient returns three or four days after injury with signs of inflammation, an attempt should be made to obtain a specimen for bacteriologic study. *P. aeruginosa* is a likely instigator.

Dr. Peterson:

Thank you. Dr. Petty, having heard all of this, would you now alter your basic care of the puncture wound?

Dr. Petty:

I think the wound care that has been recommended in the paper in New Orleans is reasonable. I still don't think I would be interested in giving prophylactic antibiotics to all patients.

Some patients have *Pseudomonas*, others *S. aureus*, and some even have fungi infections.

Dr. Peterson:

What about checking the wound in three or four days? Do you think that is necessary?

Dr. Petty:

I think it would be wise. Some patients will come back with the first sign of infection, whereas you may have to check on others.

Dr. Peterson:

I would like to add to the basic recommendations. Wounds that go through the foot should be treated like a gunshot wound that goes through any part of the body. The patient should be taken to the operating room and the wound irrigated and, if necessary, debrided under anesthesia.

The depth of a "simple" puncture wound is most important. A blunt probe should be placed into every puncture wound. This can be done in the emergency room without anesthesia, even in children. If the wound extends to bone or even just through the deep fascia, then the patient also should be taken to the operating room and the wound debrided. This adds a lot of expense and time, but if it would prevent osteomyelitis, it is worthwhile.

Dr. Coventry:

I think we are missing a very important point, and it gets back to the basics of practicing medicine—a good history. The series from New Orleans was an urban population, as I remember. There is another series that involved a construction job in which the nails were all clean, new nails. Old lumber was not used, and the worker didn't walk in the barnyard and step on old nails that were rusted and full of soil. The incidence of infection in this series was as low as 2%. So, I think it is important to ask the patient about the penetrating object. If it is an old abandoned chicken coop and a rusty nail, it is a lot different than a brand new nail on a construction job. I think it is very important not only to determine the depth of the wound, which was stressed, but also the nature of the penetrating object.

Dr. Peterson:

And, of course, the retainment of a radiolucent foreign body is a complete subject by itself.

Dr. Richard S. Bryan:

In one series of open fractures, the initial cultures never agreed with the final cultures. I am really not at all certain if the best treatment can

prevent infections. I don't think there has ever been a proved treatment to prevent osteomyelitis from occurring.

Dr. Peterson:

Do you recommend no treatment?

Dr. Bryan:

No, I would not, but I think what Dr. Coventry has said makes excellent sense.

Dr. Peterson:

The question of taking a routine Xray has not been answered. I would also base this decision on the depth of the wound, as determined by the probe. Any wound that punctures the deep fascia should be Xrayed.

Dr. Petty:

Even if it is a clean nail?

Dr. Peterson:

Yes. The nail usually goes through a shoe or something. Even though most Xrays would be negative, there could be a retained fragment of nail or rust. From a medicolegal standpoint, it would be wise to have an Xray.

I would like to stress the importance of local wound treatment when caring for puncture wound of the foot. The depth of the wound must be determined. Wound toilet must be adequate and aided by surgical debridement when necessary. Proper tetanus immunization is mandatory. The data are insufficient to prove the effectiveness of prophylactic antibiotics. But it should be emphasized that a puncture wound of the foot is sometimes not an insignificant injury.

Request for Physician's Art Work

For many years the Board of Editors of MINNESOTA MEDICINE has recognized and supported photographic and other artistic talents of the members of the Minnesota State Medical Association publishing cover pictures in color of their work. Our series of color covers have received much favorable comment and many journals have followed us in the use of color art in this manner.

We solicit color photographs including pictures of all art forms created by members of the Association. These must be technically excellent to show off the subject to its best advantage.

Although in the past we have printed cover pictures depicting many distant parts of the world, photographs of life in Minnesota will be given preference. Pictures will be returned if identified with the name and address of the physician. Please submit your picture as prospective cover subjects to the Editor of MINNESOTA MEDICINE, 375 Jackson St., St. Paul, Minnesota 55101.

Farrell Stiegler, M.D.

Medical Writing

Increasing organization in the field of medicine, as in every other field of human endeavor, has raised the level of contributions to medical literature. Far too often, however, physicians still prepare their contributions with a striving and agony and delay comparable to the delivery of human progeny by one untutored in the refinements of obstetrics.—Morris Fishbein (1889-) *Medical Writing* (3rd ed.), Introduction

Maynard Reece

Enjoy these beautiful wood ducks in your home or office

"It's a thrilling sight to see the handsome drake wood duck standing quietly on a gnarled log with his mate. Because of the wood ducks' preference for secluded timber areas near or in the water, they enjoy quiet, shaded ponds. These spots are ideal for the fragrant water lily. The lily pads floating on the clear water seem suspended in midair. Overhanging boughs add to the privacy of this dark hideaway. Wood ducks are adept at swift flight in heavy timber, darting and twisting with ease through a heavy tangle of trees."

The only FIVE TIME winner of the Federal Duck Stamp design competition.

DUCKS UNLIMITED Artist of the Year—1973.

Maynard Reece

Limited to only 550 prints, signed and numbered, this remarkable painting of wood ducks has been faultlessly reproduced using twelve different color inks on special B.F.K. Rives all rag content paper.

This is the first Maynard Reece painting reproduced by the unmatched and very expensive Collotype Process which builds up to a depth and richness of color that is faithful to the original. Plate size, 19" x 27" with ample margins. \$125 each.

Maynard Reece at work on *Feeding Time—Canada Geese*. Lithograph reproductions in eight colors of this magnificent painting are now available. Plate size, 19" x 25" with ample margins. \$75 each.

Classified advertising rates are thirty (30) cents a word; minimum monthly charge \$7.50; key number, fifty (50) cents additional.

Replies to advertisements with key numbers should be mailed in care of Minnesota Medicine, 375 Jackson, St. Paul, Minn. 55101.

FAMILY PRACTITIONER WANTED to join small progressive group serving beautiful Mille Lacs Lake area, only eighty miles north of Minneapolis. Modern clinic and JCAH seventy-three bed hospital and ECF. Excellent income potential; group support, two out of three weekends off. Away from the madding crowd; yet not too far away. Good schools; clean, uncrowded environment; lakes to live on; unfettered living. We need you. Contact: Dr. Dennis R. Jacobson, 612-532-3113 (clinic), 612-532-3628 (home), or Marshall E. Engstrom, Hospital Administrator, Community Mercy Hospital, Onamia, Mn. 56359, 612-532-3154 (office), 612-532-3693 (home).

PART OR FULL TIME, Southdale or downtown Mpls., GP or internist. Pleasant work, mainly examining executive and professional people, no weekend or evening duty. \$20 per hour part-time or \$30,000 annually full time. Free time easily arranged for outside activities or extra vacations on pro rata income basis. Special arrangements can be made for physical handicaps other than age (62 is the upper limit) or sensory loss. Must be graduate of U.S. school licensed or licensable in Minnesota. Write: MINNESOTA MEDICINE—484, 375 Jackson, St. Paul 55101.

SHELL LAKE CLINIC, LTD., Shell Lake, Wisconsin, expanding to seven man group. Three family physicians and one surgeon desire additional two family physicians and one internist. New 70 bed general hospital adjoins clinic. Excellent remuneration in corporate practice. City surrounds one of largest and finest swimming and fishing lakes in Northwest Wisconsin. Call 715-468-2711 or write to Clinic Manager Darrell Bailey.

WANTED—OBSTETRICIAN-GYNECOLOGIST—Seventeen man multi-specialist group, located in the beautiful Hiawatha Valley, 50 miles south of Minneapolis and St. Paul. Seeks Board Certified or eligible OB-GYN to join present two-man department. Full sharing in delivery and major surgery at once. No pregnancy terminations. Send curriculum vitae and brief background sketch, experience, family data, etc. Write: MINNESOTA MEDICINE-488, 375 Jackson St., St. Paul 55101.

RIVERS EDGE MEDICAL CLINIC—Farmington, Mn. needs two additional General Practitioners to practice in a nearly new Clinic, Hospital and Nursing Home. Fast growing area just 45 minutes from St. Paul-Minneapolis. Metropolitan advantage with Community living. Contact M. H. Hunter, M.D. (612) 463-7181.

EXPANDING TEN MAN FAMILY PRACTICE GROUP in southern Minnesota. Seeks GENERAL PRACTITIONER OR INTERNIST for summer of 74. New clinic adjacent to a new 114 bed hospital. Fairmont is a progressive community (City of Five Lakes). Starting salary open, early partnership opportunity. Contact D. E. Grandgenett, Fairmont Medical Clinic. 507-238-4263.

WANTED—General Practitioner for an incorporated practice. Wisconsin community of 6,800 on interstate highways. Excellent schools, recreational facilities. Modern clinic adjacent 85 bed hospital. Salary first year then partnership. Call 608-372-4177 Collect.

HELP—us form 3 to 4 man group. 60 bed new hospital. Resident anesthetist, physiotherapist County seat and industrial town. Modern clinic facilities. Supreme fishing-hunting close by. Artificial ice arena. Municipal pool and golf course. Shared education and vacation time. Good deal! Drs. Delmore and Metcalf, Roseau, Minnesota 56751.

GENERAL PRACTITIONER desired for northern Minnesota clinic located near Lake of the Woods area. Enjoy the clean air, clear waters, compatible working arrangements including ample time off for meetings, vacations and good financial arrangements. Excellently equipped hospital (acute, skilled nursing and board and care facilities.) fine clinic one block from hospital. Write: Minnesota Medicine, 473, 375 Jackson St., St. Paul 55101.

WAYZATA MEDICAL BUILDING OFFICE SUITES—Located in the fastest growing suburban area in the Twin Cities. We offer:

- Surrounding area of lakes, country clubs, woods, beautiful homes;
- Unsurpassed medical building facilities
- Fast growing area—high median family incomes
- Beautiful building—inside and out
- Inner courtyard with trees and landscaping
- Heated indoor parking
- Adjacent access to freeway system
- Low rental rates—favorable base terms
- Financial services

We have grown to fourteen specialties since our building was completed two years ago. We particularly are interested in Orthopedics, Psychiatry, Urology, Otolaryngology, Internal Medicine and Dentistry. Give us a call. We have a lot more to show you and to talk about. Reply to: Mr. Paske, Wayzata Medical Building, 250 North Central Avenue, Wayzata, Minn. 55391, (612) 473-0031.

Cadaver Organ Retrieval

Participation of the Community Hospital

A. W. MOBERG, M.D., E. G. YONEHIRO, M.D., E. A. SANTIAGO, M.D., R. L. SIMMONS, M.D. and J. S. NAJARIAN, M.D.*

ALTHOUGH POST MORTEM DONATION of various organs (kidneys, pancreas, liver, etc.) has become a humane and honorable gesture, clinical transplantation is still limited by the availability of suitable donor organs. Approximately 7,500 of the 55,000 people who die each year of primary renal disease could be helped by transplantation.¹

One potential source for cadaver organs is the community hospital where most traumatic injuries are treated. Although people have recently begun to request that their organs be procured in the event of accidental death, the opportunity for organ donation has been logistically limited. Today, improved communications between the transplant centers and outlying hospitals have overcome the problems relating to definition of donor death and maintenance of organ viability. Therefore, using new methods of organ preservation and transportation, it now seems technically feasible for all communities to participate effectively in organ procurement.

There are several advantages for initiation of a community retrieval program. Local organ procurement eliminates the need to transfer the donor and enables the family to maintain continuity of care with their personal physician. It abolishes the psychological problems of adapting to a new hospital environment and doctors unacquainted with the donor's previous care. The chance that the fatally injured donor will die before the organs can be saved is minimized, resulting in an increased number of transplantable organs. Finally, some of the usual family grief associated with an accidental death may be relieved by the opportunity for organ donation.

Criteria for Donor Acceptance

Table 1 summarizes the general criteria a potential donor must possess to be considered acceptable.

Emergency nephrectomy following an acute

death may render cadaver kidneys suitable for transplantation. More often however, the time required for nephrectomy and organ preservation yields nonviable organs. Under most circumstances, brain death must be present for organ donation to be possible from a community hospital.

Brain (neurologic) death is the most frequent circumstance leading to retrieval of cadaver organs. Under these conditions, the maintenance of a normotensive state allows time for donor stabilization and determination of organ function, acquisition of consent for donation, preparation for organ preservation and duration of travel for the organ procurement team. These organs, following various periods of *ex vivo* storage, generally function immediately upon implantation.

Definition of Brain Death

Cerebral death broadly means "cessation of life-supporting function of the central nervous system." The usual candidates for cadaver organ donation are young or middle-aged patients involved in various traumatic accidents with injuries primarily limited to the head. Recently, the traditional concept of death (cessation of heart beat and respiration) has been challenged because of increasing social and medical concern regarding the artificial maintenance of cardiopulmonary function by modern resuscitative equipment. Such support in the presence of a hopelessly injured

TABLE 1	
Criteria for Consideration as Organ Donor	
A.	Neurologic death (all causes) with certainty of the absence of spontaneous respirations.
B.	Age limit of 65.
C.	Absence of systemic sepsis.
D.	Absence of generalized malignancy (outside CNS).
E.	Absence of premortem disease of the potential transplantable organs, i.e., history of renal disease.
F.	Reasonable expectation for maintenance of stable cardiovascular state and organ function, i.e., urine output.
G.	Consent for organ donations from the relatives of the decedent (Table 7).

*Department of Surgery, University of Minnesota Hospitals Minneapolis. See editorial, page 773.

central nervous system only serves to maintain a vegetative state without justification. A redefinition of death based on the integrity of the central nervous system is preferable, in view of the mechanical ability to prolong a vegetative state indefinitely. The termination of supportive measures not only reduces the suffering of the patient's family and their economic burdens but it also enhances the effectiveness of the medical staff caring for such a patient. It is of secondary importance that this circumstance is ideal for making available cadaver organs suitable for transplantation.

The definition of the state of cerebral death was the subject of an Ad Hoc Committee of the Harvard Medical School in 1968.⁴ According to the criteria which they accepted, cerebral death exists under the following circumstances:

1. No spontaneous respiration.
2. No superficial or deep reflexes (pupillary light reflex included).
3. No movements either spontaneous or secondary to painful stimuli.
4. Electrocerebral silence by electroencephalogram (EEG).
5. All of the above findings should show no change 24 hours later.

These criteria have recently been modified by the Neurosurgical Department of the Minnesota Health Sciences Center.⁵ The amended criteria of brain death are summarized in Table 2. Within our center an unresponsive EEG is not mandatory. Although a great deal has been written on the prognostic value of the EEG, the degree of activity necessary to be compatible with functional recovery of the central nervous system is not known. It may be used as a confirmatory test of the clinical judgment, but in the absence of agreed prognostic value the necessity for an EEG to pronounce cerebral death is unproven. Much more reliance must therefore be placed upon clinical judgment.

At the community hospital, reliance upon the EEG will depend upon the availability of a consulting neurologic or neurosurgical staff for clinical opinions as well as the interpretation of the EEG. Dependence upon this test is a matter of joint decision between the medical and administrative hospital staffs. A committee comprised of a neurologist, family practitioner and an internist may make the pronouncement of "brain death" according to the outlined criteria (Table 2).

Maintenance of Organ Function after Brain Death

When cerebral death has been pronounced and donor acceptance determined, management involves the maintenance of the cardiac, pulmonary and organ functions. An appropriate management plan consists of the three following broad categories:

1. Documentation of satisfactory organ function (renal status).
2. Supportive measures for cardiopulmonary system.
3. Supportive measures for renal function.

The important facts that must be documented before acceptance as a kidney donor are listed in Table 3. In cases of trauma there is frequent slight hematuria which does not preclude utilization of the organs. Often, premortem oliguria is iatrogenically induced by dehydration during treatment of cerebral edema in the neurologically injured patient. Oliguria explained on this basis does not exclude organ donation since urine output is usually corrected by adequate parenteral therapy. Renal failure secondary to the hepato-renal syndrome does not eliminate the use of those kidneys, since renal function will return upon implantation into a new host.

TABLE 2
Criteria of Cerebral Death

1. No spontaneous movement
2. No spontaneous respiration when tested for period of 4 minutes at a time.
3. Absence of brain stem reflexes:
 - a. dilated and fixed pupils
 - b. absent corneal reflexes
 - c. absent ciliospinal reflexes
 - d. absent Doll's head phenomena*
 - e. absent gag reflex
 - f. absent vestibular response to caloric stimulation
 - g. absent tonic neck reflex
4. A status in which all of the findings above remain unchanged for at least 12 hours.
5. Brain death can be pronounced only if the pathological processes responsible for the above are deemed irreparable with presently available means

*Absent proprioceptive head-turning, also called oculocervical reflex.

TABLE 3
Documentation of Renal Function

1. Absence from history of previous renal disease such as hypertension, frequent infections, diabetes.
2. Normal urinalysis.
3. Satisfactory values for BUN, creatinine, electrolytes, blood sugar, and a two, 12 or 24 hour creatinine clearance.

Table 4 summarizes the desired parameters which indicate ideal support of the cardiopulmonary system ($BP > 100$; $P < 120$; CVP 10-15). The use of vasopressor drugs to achieve these values is avoided when possible. Satisfactory circulatory support can be maintained with adequate volumes of intravenous fluids and appropriate pharmacologic agents (Digitalis, electrolytes, antiarrhythmia therapy). In our experience, vasopressive agents are rarely required—when necessary Isuprel (10 ml of 1/5000 in 500 ml D_5W and 1 amp of $NAHCO_3$) is given by microdrip at a rate which maintains blood pressure.

TABLE 4	
Ideal Systemic Parameters	
Blood Pressure	> 100 mmHg Systolic
Pulse	< 120 /min
Central Venous Pressure	10-15 cm H_2O

The appropriate intravenous therapy required to stimulate urine output (100 ml/hr) is listed in Table 5 and consists of equal volumes of both a colloid and crystalloid solution. After initial hypovolemia is corrected, a crystalloid solution (D_5W $\frac{1}{2}$ NS with 25 mEq/L KCl) is administered at a rate which enables hourly replacement of urine volumes. An equal volume of the colloid solution (Plasmanate) is given as required to support blood pressure and central venous pressure. The CVP may rise in response to fluid administration without adequate urine output. In this case, urine is stimulated by giving a Lasix and Mannitol solution (500 mg Lasix in 500 ml 20% Mannitol at a rate which maintains urinary output at 100 ml/hr).

Technique of Organ Procurement

Organ retrieval is best accomplished by a group

TABLE 5

Maintenance of BP; CVP; Urine Output

1. Increase CVP to 10-15 cm H_2O by correcting any initial hypovolemia with whole blood or plasma (plasma protein fraction); BP usually responds.
2. Maintain BP > 100 mmHg; CVP $> 10-15$ cm H_2O with a colloid solution (plasma, plasma fraction, blood) given in volumes* as required.
3. Maintain urine output at 100 ml/hr by administering a crystalloid solution (D_5W $\frac{1}{2}$ NS with 25 mEq/L KCl) in a volume* equal to the hourly urine output.
4. Low urine output in the presence of adequate BP, CVP, and fluid administration can be corrected with Lasix and Mannitol solution (500 mg Lasix in 500 ml 20% Mannitol) given at a rate sufficient to stimulate urine production.

*The volumes of the colloid and crystalloid solution should be approximately equal. The crystalloid solution when given alone often is not sufficient to maintain BP and CVP.

comprised of both intrinsic interested physicians on the local medical staff and a surgical procurement team from the transplant center. Success of any community organ procurement program depends upon the establishment within the local hospital of a team composed of both physicians (internist, nephrologist, surgeon, neurosurgeon, neurologist) and paramedical personnel (hospital chaplain, charge nurse, etc.) on the case. This group (liaison team) should be separate from any surgeon to minimize any possibility of "vested interest." This team would assist the potential donor's primary physician in:

- A. Determining suitability for organ donation.
- B. Obtaining permission from the next of kin (Table 6).
- C. Preoperative donor management to maintain maximal organ viability and function.
- D. Intrahospital logistical cooperation between all concerned.
- E. Create for the relatives the smoothest pos-

sible transition from acceptance of death to granting permission for organ donation.

F. Maintenance of an appropriate hospital image.

The prerogative of the donor's primary physician to become involved in organ procurement should be his choice. Although he may wish to maintain continuity of care and family rapport throughout declaration of death and organ donation, the intrahospital liaison team should be organized such that the primary physician need only contact them to handle the matter.

The composition of the liaison team should be sufficiently broad so that all matters concerned in organ donation are adequately organized. This includes assistance in determination of donor death, preoperative donor management, and understanding of nursing and operating room procedures. Of equal importance is the establishment of a proper relationship with the relatives and the community to avoid adverse hospital publicity,

and to enhance the image that the community hospital provides high quality primary medical care.

Upon notification by the primary care physician of a potential donor death, the liaison team should insure that the prospective donor meets the basic criteria for organ donation (Table 1). If so, the surgical procurement team from the transplant center* should be notified; they will then proceed to the local hospital to assist in removal of the usable organs and initiation of organ preservation procedures.

During the operative removal of kidneys, every effort is made to maintain them in the diuretic state induced prior to the nephrectomy. Care is taken to avoid vasospasm in the renal arteries by gentle handling of the organ. In cases where multiple renal arteries are found, preservation and subsequent renal transplantation is augmented if the kidneys are resected "En Bloc" with a segment of aorta and vena cava, as utilized in

*University of Minnesota: Telephone 612-373-8322.

Figure (Left)—Transport Module. Measures 43 cm x 33 cm x 54 cm and weighs 30 kg. Operates on standard A/C or independent battery power. The organ cassette is easily transferred to the hospital console following disengagement of pump, temperature, air and heat exchanger connections.

(Right)—Hospital Console. Provides the cassette with a pulsatile pump, a gas source for air, CO₂, O₂ and Freon refrigeration with constant temperature regulation. The simplified control panel is easy to operate; minimal supervision is required. Renal artery pressure and plasma flow is controlled by the stroke volume and pulse rate; pH is maintained by appropriate CO₂ and O₂ gas flows.

(From Moberg AW, Santiago EA, Mason RV, Mozes MF, Campos RA and Najarian JS Transportable organ-perfusion system for kidney preservation. *The Lancet* 2:1403, 1971.)

rapid nephrectomy.

Prior to organ removal the following agents are given intraoperatively:

1. Methylprednisolone (SoluMedrol)—30 mg/kg given 1 hour prior to nephrectomy.
2. Patients are systemically heparinized (20,000 units) prior to nephrectomy.
3. The previously described Lasix and Mannitol drip is given intraoperatively to maintain urine output.
4. Ten minutes prior to nephrectomy one ampule Mannitol is given intravenously to induce a final diuresis.

The removed kidneys are immediately placed in a basin of cold sterile saline and in sterile saline ice cubes. The renal arteries are cannulated and the kidneys flushed at 4°C with medicated Ringer's lactate (10 ml Heparin, 10 ml 1% procaine). Other special agents or solutions which potentially could be required are summarized in Table 7.

Role of Organ Preservation Techniques

The development of successful organ preservation techniques now permits the *ex vivo* maintenance of organ viability. These methods allow the use of kidneys retrieved in distant hospitals. The preservation technique employed utilizes *ex vivo* organ perfusion with cryoprecipitated plasma under hypothermic conditions using an apparatus designed at the University of Minnesota (Figure). This apparatus permits transportation and storage of organs up to 72 hours.

TABLE 7
Specialty Items Required for Organ Procurement
The following items are required at hospitals participating in cadaver organ retrieval:

A. Medications

- Lasix—Up to 2 gm/patient
- SoluMedrol—Up to 3 gm/patient
- Mannitol—Up to 500 ml of 20% solution
- Heparin
- Low Molecular Weight Dextran (Dextran 40 and Rheomacrodex)
- Plasma substitutes
- Purified Protein Fractions
- Plasmanate, etc.

B. Surgical Equipment:

1. A general laparotomy tray, and vascular equipment (arterial and venous clamps with vascular suture)
2. Chilled Ringer's Lactate (4 one liter bottles at 4° C) for washing of kidneys
Added to the Ringer's Lactate are:
a) Procaine—10ml (1%)
b) Heparin—10 ml (1000 units/ml)
c) NaHCO₃—5 ml
3. Two to four trays of sterile frozen normal saline
4. Sterile IV fluid administration sets.

Financial Considerations

In the past, a recipient's insurance carrier has reimbursed all costs of organ procurement, including hospitalization costs beyond pronouncement of death, medications, use of the operating room, surgeon's fee, and fees of ancillary personnel on the liaison team. In the event that such costs are not met by the insurance carrier, all reasonable costs of organ procurement will be borne by the Department of Surgery at the University of Minnesota from research funds designated for this purpose.

COUNTRY LIVING-METROPOLITAN CONVENIENCE—WANTED AND NEEDED: One or two General Practitioners to set up practice in new and equipped clinic with utilities paid and rent free 6-12 months. Service area of 9,000 and rapidly growing. New hospital in planning stages, new high school under construction. Located within one hour of Minneapolis-St. Paul. Dental, Veterinary, and Mental Health Clinics also located here. Golfing, bowling, fishing, hunting, etc. in area. Interview expenses and all moving expenses paid. Join us for comfortable country living with big city benefits. Try it, you'll like it! Write: MINNESOTA MEDICINE—485, 375 Jackson, St. Paul 55101.

A BETTER PLACE TO PRACTICE MEDICINE. For those who would prefer to live in a warmer climate, avoid the big city school, traffic and practice problems; contact this multi-specialty group, located in a city of 100,000 people in North Central Texas. Specialists in Internal Medicine, Family Practice, Pediatrics, General and Orthopedic Surgery are needed to complement the current staff of twenty-one full time physicians. Wichita Falls Clinic-Hospital, 1300 Eighth, Wichita Falls, Texas 76301.

WANTED—Recently trained radiologist to provide modern diagnostic and therapeutic radiological services for a recently consolidated midwest regional hospital of approximately 300 beds. Radiologist recently expired and his part time associate plans to retire soon. Write: MINNESOTA MEDICINE-492, 375 Jackson, St. Paul 55101.

FAMILY PHYSICIANS needed in the community of Tracy, Minn. New clinic being built to accommodate 4 doctors in a clinic setting. Excellent opportunity. Contact Administrator, Tracy Municipal Hospital, Tracy, Minnesota 56175, phone 507-629-3200.

LOCUM TENENS WANTED—G.P. for coverage in Oct. and Nov. 1973 in northern Minn. community with 60 bed hospital adjacent to four medical clinics. Write or call Fred Martin, M.D., Clearwater Clinic, Bagley, Minn. 56621. Ph 218-696-6281.

NEEDED IMMEDIATELY—Two general practitioners to locate in Northwest Iowa, close to Iowa Great Lakes. New medical clinic, very modern hospital serving a large area and very lucrative practice. Excellent financial arrangements. Call or write: Ivan E. Brown, MD, 551 West Maple Drive, Hartley, Iowa 51346, Phone 712-728-2820.

MAPLEWOOD LOT FOR SALE—Excellent location for small Medical office—possibly a branch office. Please call 770-3831.

INTERNIST-FAMILY PRACTITIONER to join three Family Practitioners and one Board Certified Surgeon in Incorporated group practice. Only 60 minutes north of the Minneapolis-St. Paul area with easy access to lakes and outdoor sports. Facilities include New Clinic, 63 bed general hospital with ICCU and 87 bed nursing home, all new. Call or write: Larry J. Brettingen, M.D., 224 7th St., Mora, Minnesota 55051, Ph. (612) 679-1313.

METROPOLITAN-ST. PAUL FAMILY PRACTICE—Immediate opportunity for 1 or 2 Family Practitioners to replace 1 member leaving for industrial practice. 5-man professional association with active and varied practice. Salary with percentage and early association if mutually desirable. All inquiries held in strict confidence. Write: MINNESOTA MEDICINE-491, 375 Jackson St., St. Paul 55101.

PHYSICIANS ASSISTANT—Graduate University Washington MEDEX program. Three years Special Forces medic, one year with GP. Resume upon request. Michael Erkel, Route 2, Box 142, Kimberly, Idaho.

Alcohol Treatment Centers Problems and Recommendations

MILTON H. SEIFERT, JR., M.D.*

THE ADVENT OF THE treatment center for alcoholism (especially into the hospital setting) was welcomed by many, but especially by physicians involved in primary health care. The perspective of time now tells us that this complex disease is still difficult to treat and that the treatment center approach does not guarantee a good result.

While a treatment center seems to have improved the success ratio, physicians are now being faced with an increasingly prevalent problem and that is the alcoholic patient who is a treatment center failure. Whatever else is said about this entity, it must be viewed as a serious complication of the disease process.

In the reassessment of treatment center procedures, it seems possible that first, the treatment center may not be providing the basic components of health care delivery, and secondly, the treatment center may not be making enough use of the primary health care physician, especially the personal family physician. That these two facts are related to each other and they in turn are related to the complication of treatment center failure is the point of this paper.

Treatment center policies reveal that there is an attitude of secondary importance with respect to the physician services and personal and family health care services. Some centers have only one physician-director, and in others, a patient may choose his own physician or take a physician on "rotation." One policy states that the patient "will in effect become a patient of the (hospital) for the duration of his stay in the (treatment center)." A policy has not been found requiring the physician to have any special qualifications nor one that defines a role for the physician as an integral part of the treatment plan. Nor has a treatment center policy been found that recognizes a necessary interdependence on the other health care resources. This attitude should be considered as one that could compromise the therapeutic

efforts of the alcohol treatment professionals.

In the Alcoholic Anonymous (AA) community there is suspicion regarding the competence of the physician to deal with the disease of alcoholism. To some extent this prejudice has carried into the treatment center and has hampered the function of physicians. In some instances, the physician has been met with rejection because he himself was not an alcoholic, he was not formally trained in the alcohol counseling techniques, or he was being held responsible for alcoholics who had done poorly because they had controlled the management of their own care.

An inadequate role definition with its attendant inadequate physician participation is not in our best interests. It is bad for the physician who has an educational need in this area and for the patient if the physician was competent in the first place.

In the process of the redesign of treatment center procedure, consideration should be given to the disease itself, the basic components of health care delivery, and the skills and perspectives of the family physician. Alcoholism is a family disease that is common, chronic, progressive and multifaceted. The basic components of health care delivery are availability, comprehensiveness, effectiveness, continuity and individualization. The special capabilities of a family physician enhance the probability of delivery of the basic health care components.

The family physician can contribute to increasing the success of treatment by being available for the early diagnosis and treatment of a common disease and for crisis intervention. A generalist almost by definition is better able to see the need for and thus advocate a comprehensive set of health services. Effectiveness of treatment can be insured by the ability of a family physician to provide an ongoing assessment of the treatment program in terms of both the patient and his family. The privileged relationship that a family physician has to his patient and to the family provides

*A Family Physician in General Practice.

Address reprint requests to: Milton H. Seifert, Jr., M.D., 675 Water Street, Excelsior, Minn. 55331.

pre-existing trust that can be useful in the face of alcoholic rationalization. Pre-existing insights allow for individual application of the comprehensive resources. If the whole treatment team would allow it, the family physician could reduce unnecessary fear by offering the patient a real measure of personal protection especially when a particular treatment modality makes the patient worse.

The delivery of continuity may be the most valuable of the basic health care components in the treatment of alcoholism. An incurable, lifelong, chronic disease always requires continuity. Often, the delivery of continuity in health care depends on a continuing relationship with a health professional. The patient leaves the treatment center eventually, and usually gravitates away from the outpatient program as well. But a continuing relationship with a personal physician is a natural sort of thing. Whenever any treatment program is shown to be inadequate (such as when the patient is about to become a treatment center failure), a family physician can quickly move into the breach, negotiate the revision of a new treatment plan, maintain continuity, and, prevent the treatment center failure complication.

Alcoholism is, by definition, a family disease, and the treatment effort ought to require the participation of a family physician specialist for each patient. It has long been accepted that the non-alcoholic family members are just as sick in their own way and in need of an intensive treatment program too. It is here suggested that a successful treatment team should include the following: the patient; his physician; the family; a recovered alcoholic; and, a spiritual advisor. Other services that may indeed be necessary for survival are usually quite adequately provided in the treatment center setting.

With these thoughts in mind, the author urges that treatment center policies deal more realistically with the disease of alcoholism as we know it, and, at the same time, make better use of the available health care resources. The recommendations are as follows:

1. The treatment team should include a general physician, preferably one who has a pre-existing relationship with the patient and his family.
2. The functional role of the family physician should be defined in terms of the disease process and the natural capabilities of this professional.
3. The treatment team should use a problem-oriented medical record, especially as it applies to the problem list, i.e., a listing of all of the patient's physical, mental and social problems. This will insure a more comprehensive approach.
4. Provisions for long term continuity of care should be defined and include other health resources as appropriate.
5. There should be developed a treatment center definition of an interdependent treatment team, having the participating team members define their roles and their dependence on other team members.
6. All members of the interdependent treatment team should participate in decision making in the following areas: a) the suitability of the patient for treatment; b) the suitability of the treatment for the patient; c) the ordering of the treatment priorities in relation to the patient's comprehensive problem list; d) design of a family treatment plan; e) revision of treatment plans for the patient and his family; f) assessment of the patient's progress; and g) planning for discharge and long-term maintenance.

Summary

While the family physician welcomes the help of the alcohol treatment facility and notes its improved results, he finds that he is not considered necessary in the treatment program, and, in some cases, even finds himself unwelcome. This would be acceptable if the treatment center had produced a uniformly good result.

It would seem that the treatment center, by its attitude and its policies, does not generally appreciate the capabilities of the personal family physician. This article has outlined the ways in which this health care professional might materially contribute to the success of the treatment center effort.

A revision of treatment center policies is suggested, and to this end, some specific recommendations have been made.

R. F. Schmidt, M.D.

Dr. R. F. Schmidt was honored by Alden on occasion of his twenty-five years of service to that community.

Just what do you get for your AMA dues?

You get a package of personal and professional services and benefits you've probably never been fully aware of.

You get insurance programs at a cost considerably lower than those purchased on an individual basis. A \$250,000 Excess Major Medical Policy. Group Life. Disability Income Insurance. Professional Liability Insurance (in co-sponsorship with your state society.) Then there's the AMA Members Retirement Fund.

You get a comprehensive medical library to help you do your research. An editing service for your articles. Information and reports on

medical and health subjects from any AMA department.

You get publications to keep you abreast of medical and health developments. *JAMA*. *American Medical News*. And *Prism*, the new socioeconomic journal.

You get the Physician's Placement Service to help you find a place to practice or locate an associate. And if you're a resident winding up your training, there's a special workshop to help prepare you for setting up your practice.

All these are just a few of a broad spectrum of benefits and services you get for your dues. But even more important, you get a strong and effective national spokesman to represent you, your interests and your views.

Join us.

We can do much more together.

"Too many doctors are dependent to the economic consequences of their decisions." So stated an issue of *Medical News Report* (December 4, 1972), an independent weekly newsletter published by AMA Chief Executive F. J. L. game, M.D.

Doctor, are you indifferent...

In discussing an anticipated increase in Blue Shield rates, *Blue Shield's* newsletter had this to say:

"In general, it can be said that we have given the impression that we are not particularly concerned with the increase in cost of health care to patients..."

"True, an MD's training is primarily scientific, but in the real world of practice, all of his scientific decisions have a price tag, or an economic impact. The economics of health care beckon the practitioner's attention. Concern for economics of medicine is a reality."

When the pharmacist recommends that a drug product other than the one ordered be dispensed, the prescriber invariably permits the change when he feels the best interests of the patient will be served.

Shortcomings of Pro-Substitution Argument

The fact remains that it is necessary for the prescriber to know the change is being contemplated and to be in a position to concur or demur. Without that opportunity for unilateral decision of the pharmacist made in the absence of clinical knowledge of the patient, could expose to needless risks, and in addition jeopardize the relationship between the professions of Pharmacy and Medicine. In my view, there is no offset in the pro-substitution argument to offset these risks.

The Issue of Drug Knowledge

Substitution advocates claim that the primary justification for changing the rules is the desire to better utilize pharmacists' knowledge about drugs. Yet the pharmacist's task to keep current on the ever-changing field of drug therapy, to some extent puts him at a disadvantage. Most often, a practicing physician with expert knowledge of no more than

Too many doctors are indifferent to the economic consequences of their decisions. Too many, for example, habitually hospitalize patients for the convenience of the MD. It's time to deny such habits exist. . . . Doctors, thru their medical societies, have unhesitatingly appealed to the patients for support in the fight against government interference in the private practice of medicine. The public in the past has responded. It's time the American Medical Association and state and local medical societies paid off the debt by their action to hold down the cost of medical care."

Drugs

Insurance rates and hospital
are only two factors in health

care costs. The cost of drugs—both prescription and nonprescription—is another.

And when it comes to drug costs, the nation's pharmacists are *concerned*. Through their national professional society, the American Pharmaceutical Association, pharmacists are advising the public to use nonprescription medication cautiously and conservatively, and to seek the advice of their pharmacist before selecting or purchasing such drugs.

Outdated Laws

The pharmacist also is aware that when it comes to prescription drugs, often he has an even greater opportunity to reduce the cost to the patient—with no sacrifice in the quality of the medication dispensed. But in many states, outdated and antiquated laws prevent the pharmacist from engaging in drug product selection. “Drug product selection” simply means that the pharmacist functions in the patient’s interest by consciously choosing, from the multiple brands available, a low-cost quality brand of the specific drug to be dispensed in response to the physician’s prescription order.

Much *misinformation* has been purposely spread by those who stand to gain financially by maintaining

high drug costs to the public. An endless stream of propaganda has emanated from the drug industry in an effort to persuade the medical profession that these so-called anti-substitution laws should be retained. And as long as these laws are retained, the drug industry will continue its current marketing practices which contribute unnecessarily to high drug costs to patients. These practices also are inviting government agencies to expand their restrictive controls on physicians and pharmacists.

APhA Efforts

As pharmacists, we are concerned about health care costs. We hope that every physician shares our concern on this vital issue, and will give his personal support to the constructive efforts APhA has undertaken in the interest of all patients.

(For a complete discussion of drug product selection, you are invited to request a free copy of the "White Paper on the Pharmacist's Role in Product Selection" from: American Pharmaceutical Association, 2215 Constitution Avenue, N.W., Washington, D.C. 20037.)

Drugs that he selects to treat the variety of conditions encountered in practice. Moreover, the physician's choice of a specific brand is based on his knowledge of the patient's medical history and current condition, and his experiences with particular manufacturer's

Some substitution proponents argued that the dispensing of a substitution is a simple two-party transaction between the pharmacist and the patient, and that a substituting pharmacist may avoid even a minimal breach of contract by simply informing the patient that he is making a substitution. I would judge that courts would be sympathetic to a pharmacist who substituted without physician approval and who took a legal defense that seeks to make the patient responsible for the pharmacist's actions.

Would Prescription Prices?

stitution advocates are arguing to the consumer, and partly the consumer activist, that a change in prescription prices could be achieved through the legalization of substitution. There is seen absolutely no evidence to support this claim. To the contrary, the experience in Alberta, Canada, where substitution is authorized, suggests

the opposite.

Many pharmacists understandably are concerned about the cost of maintaining multiple stocks of similar products. While there is no doubt that inventory costs rise when additional brands are stocked, it would be interesting to know how much they rise, and how many pharmacists actually stock all brands—of, say, ampicillin or tetracycline—or how long they keep “slow moving” products on their shelves before they are returned for credit. To ask that the industry eliminate multiple sources is to ask competitors to stop competing.

Drug Substitution—A License for the Unethical

Anti-substitution repeal would favor "corner cutting" pharmacists and manufacturers. For them, free substitution would be not a right, but a license. As an aftermath, it is quite likely that the confidence of both physicians and patients in the profession of Pharmacy would be eroded, as revelations about the unconscionable behavior of an undisciplined few were magnified in the press or in professional circles.

Summary

In short, what the American Pharmaceutical Association advo-

cates as a broad-spectrum panacea looks to us to be not only a minority view (advocacy of substitution is by no means a uniform policy in Pharmacy), but also an extraordinarily costly and ineffective remedy, whose side effects are odious. We believe (1) that an impressive majority of pharmacists prefer to work with Medicine and with industry, for the consumer, and for the general good, (2) that they seek the privilege to substitute when the patient might gain and when the patient's doctor agrees, and (3) that they seek to work for the resolution of genuine grievances openly and professionally.

(For amplification of PMA views, please write for our booklet, "The Medications Physicians Prescribe: Who Shall Determine the Source?" It is available from: Pharmaceutical Manufacturers Association, 1155 Fifteenth Street, N.W., Washington, D.C. 20005.)

Book Reviews

LAW OF HOSPITAL, PHYSICIAN AND PATIENT—(THIRD EDITION), Emanuel Hayt, LL.B., Lillian R. Hayt, M.A., J.D., and August Groeschel, A.B., M.D., M.S., F.A.C.H.A. Physicians' Record Company, Berwyn, Illinois. 1205 pages.

A large portion of the contents of this well-bound, hard cover book dealing with a tremendous fund of valuable medical-legal knowledge is almost completely lost to the reader who wishes to look up a specific problem, principally because of a lack of an adequate index to guide him to the numerous pearls within. Only eight pages of topic index!

Though I found the book fascinating and well worth having for reference work, less than 10 percent of my immediate concerns could be found in the index.

There is an index of cases, which is also almost meaningless, for these are not categorized in any manner that might disclose the nature of the case. There are IX pages of contents with chapter headings and subheadings, but if I wished to look up the medical-legal considerations of for instance, witnesses, contributory negligence, erroneous diagnosis, reckless treatment, hospital pharmacy, or slippery floors, only by a remote chance would I have found these items after carefully scrutinizing approximately 1000 pages. The right hand page headings representing the chapters are excellent and helpful, but insufficient to provide an index for such a large volume of desperately needed information.

If—as is occasionally the case—the publisher insisted upon preparing the index, the authors should not have permitted it, for only they know where the jewels lie.

The reader will have to hunt.

Carl O. Rice, M.D., Ph.D.
Editor Emeritus

FUNDAMENTALS OF CHEMOTHERAPY, William B. Pratt, M.D., Oxford University Press, 1973. \$6.95 paperback.

This is a fairly short up-to-date text intended for the medical student, graduate student in pharmacology, and the physician and deals with antibiotics and other chemotherapeutic agents, classified according to their biochemical site of action. In order to understand the author's explanation of the mechanism of action of the various drugs, one needs to be fairly familiar with current concepts of cellular biochemistry. There are ample references to recent research studies, including quite a few extrapolated tables of data. In only a few instances is there any reference to recommended dosages, and therapeutic indications are dealt with only briefly in most cases.

There is considerable emphasis given to drug resistance and drug interaction, although there is no attempt

to make an exhaustive coverage of all the many examples of drug interactions.

I would not recommend this book for the average medical student or clinician, if this were to be the only reading on antibiotics. For those with a special interest in biochemistry and pharmacology however, is a worthwhile publication and is reasonably cheap being in paperback form.

Linda Thompson, M.I.
Minneapolis, Minn

PANCREATITIS, Earl E. Gambill, M.D., M.S., F.A.C.I. The C. V. Mosby Company, St. Louis, 1973, 302 pages and price: \$28.50.

This beautiful monograph on Pancreatitis comes to us from the Mayo Clinic and covers all aspects of pancreatitis in 16 chapters. Earl E. Gambill wrote six chapters in addition to the Introduction, and four chapters are contributed by gastroenterologists, one chapter by a radiologist, and one chapter by a surgeon.

Although the subject is discussed with clarity and completeness in every field, one gains the impression that the book is especially strong in its chapter on the Normal Pancreas, and in some chapters on Clinical Evaluation.

Occasionally one has the feeling that the author of a chapter was not quite sure how much of his field another author would cover in another chapter. Rather than refer the reader to a page, he is referred to a chapter number or chapter heading, which necessitates going back to the Table of Contents to find the reference. For example, in searching for the techniques of the Secretin Test in Chapter 9 by Gambill on Laboratory Tests in Pancreatitis, one finds it mentioned only in one sentence and is referred back to Chapter 2 by Go and DiMaggio on the Normal Pancreas. The discussion of the test in this chapter, although very thorough and accurate, is not very practical. A better description is found in Chapter 3 on Exocrine Pancreatic Function Tests. I found no mention of treatment of pancreatitis with Trypsin inhibitors or Trasylol in the Subject Index or in the text. This may well reflect the attitude of the authors to this mode of treatment, but one would like to find a critical discussion in an extensive monograph of this type anyway.

In the Chapter on Surgical Treatment of Pancreatitis I tried to correlate the more recent literature on near total pancreatectomy with the text, which was difficult because the reference numbers in discussing diverse procedures jumped without rhyme or reason. I did not find this inconsistency in other chapters.

Although the publication date for this book is given as May of 1973, it was probably written one year earlier and thus has no reference to the very new and promising fiberoptic techniques of cannulization of the papilla of Vater, common bile duct, and pancreatic duct.

These small defects should not detract from the value of this authoritative and otherwise complete treatise on pancreatitis. It is a fine addition to every physician's reference library.

H. W. Heupel, M.D., Ph.D.
Minneapolis, Minnesota

Health Care in a Doctor's Office*

IRVING ERSHLER, M.D.†

I AM INTERESTED in providing for people a much more thorough type of health program than is usually carried out in a doctor's office. I am concerned about the problems that people have in trying to get help from a doctor once they become sick with what we would call chronic disease of any sort. The most frequent and probably the most serious of these are cancer, heart trouble and emotional illness. With these three particularly, the results of treatment are often unsatisfactory. However, what many people do not understand is the fact that, once they get sick with chronic disease, the trouble they have in trying to get help from a doctor is due largely to the way they think about medical care. You go to see a doctor when you feel sick, but when you feel well it is not necessary. Chronic disease may begin very quietly in a person's body and is usually present for a long time before bothering a person at all. If we take cancer for an example, a person with cancer will usually go along for months, in some cases a year or longer, after the cancer starts growing in the body. During all, or most of this time, he feels well, looks well and would have no "reason" to see a doctor. Today with the availability of modern diagnostic or preventative medicine, if that person were examined during the early stage of cancer, examined thoroughly and I want to emphasize the word thoroughly, a surprisingly high percentage of cancer can be found at this early stage and can be cured with modern surgery, radiation, etc. Unfortunately, this doesn't usually happen. The reason is simply the way people think about medical care.

During the early curable stage of cancer, a person feels well, doesn't see any reason to go to a doctor, so nothing is done in the way of an examination. Cancer, like most chronic diseases is slowly progressive, gradually gets worse and finally reaches a stage that makes the person sick in some way. At this point a person feels that he should see a doctor. Diagnosis at this time is usually easy. However, in most cases, cure is

no longer possible. This is where the idea comes from that nothing can be done about cancer. This is why treatment of so many chronic diseases is still much poorer than it ought to be. This whole situation could be improved if we could get people to change their thinking about medical care and do several things that most people still don't do at all. They have to consult a doctor even though they feel perfectly well. They have to be examined thoroughly in spite of the fact that they feel well. In fact, the better they feel, the more thorough the examination should be, not the other way around, the way most people think.

The usual examination in a doctor's office is by no means thorough enough for this purpose and this is one way that I differ from most doctors so far as my office work is concerned. My office is arranged so that we can do all the tests that are practical to do in an office that may give us information about chronic disease of any type, and we do all these tests with every person that I take care of regardless of what their complaints may be. If a person were to come in and tell me he felt perfectly well and just wanted a "little check-up," he would get exactly the same examination as everyone else. This type of examination should be followed by a plan that would involve regularly scheduled examinations, even though a person felt entirely well. In other words, I feel that if a person is going to have the best medical care by modern standards, if he is going to be able to take advantage of what is available in the way of preventive medical care, and if he is just going to do what is possible to do to protect himself from getting into a hopeless situation with chronic disease, he has to follow a program of regular, thorough examining even though he feels well.

There is one other important factor in good medical care that I want to mention briefly and that is what I choose to call the services of a personal physician. I feel that the personal physician has to accept several responsibilities if he is to provide good medical care. To begin with, he should be the one to do the thorough examinations that I mentioned. Most doctors are so busy, they

*Verbatim Reproduction of Orientation Talk with all Prospective Patients.

†University of Utah Medical Center, Salt Lake City, Utah.

see so many patients in any one day, that the limitations of time alone make it impossible for the doctor with the usual type of office practice to do this type of work. This means then, if a doctor is going to accept the responsibilities of a personal physician, he has to be willing to limit his practice to a smaller group of patients compared to what most doctors see so that he will have time to carry out these thorough examinations. The personal physician should be someone whom patients can see at any time, between regularly scheduled examinations, so that they can discuss any problems that may occur on a day-to-day basis, regardless of what the problems may be, an ache, a pain, a cold or an emotional upset. The patient should be able to discuss such problems with the personal physician as they come along. I don't mean to imply that one doctor can treat everything. Medicine is getting more and more complicated. No one can do everything well. Doctors vary in the way they are trained. For example, in my own case, I don't do any surgery. I don't deliver babies. I don't do any nose and throat work. In spite of these limitations, I like to have my patients feel that I am their personal physician. Any time that they have any questions about themselves, they always have someone to talk to, someone whom they know and who knows them. If the problem is something that I can take care of, I am glad to do it. If it is something that I can't take care of, it is my responsibility to make sure that the patient is referred to the doctor who is best qualified to take care of that particular problem. People have difficulty finding out what any doctor is well trained to do. If they have a special problem, it is important that they get into the hands of the right doctor. This is what I mean by the role of the personal physician in medical care. This, plus a program of regular thorough examinations, are the things that are of importance in good medical care and what I try to do for people whom I take care of.

In order to provide this type of care, I have a regular plan that works out this way. A diagnostic study comes first. This just means as thorough an examination as it is possible to do in the office. It takes on the average of about four hours. The findings are discussed with the patient. He is told exactly what has been done, what the tests show, what the problems are and what can be done about them. Then I set up a regular schedule of follow-up examinations. The first

follow-up is at six months. This usually takes about an hour and a half. Once a year I repeat the original examination. A card is sent to remind the patient when it is time for the next scheduled examination. This will mean that every patient will be examined thoroughly and regularly, even though he feels entirely well. In between such examinations a patient is free to come in anytime he has a question about himself. I will take care of any problem I can. Or I will refer the patient to the doctor who is best qualified to take care of that particular problem.

This is the office plan that I use to provide the best possible medical care. It involves a good deal more thorough examining than most people have ever had. This is nothing more than what every person should have, even though they feel perfectly well, if they are going to have good medical care.

One other question that is frequently raised in regard to the problem of office practice based on a flat annual fee instead of the traditional fee-for-service basis is the question of over-utilization. This has never been a problem in my own practice. I would venture several possible explanations. All scheduled examinations are done thoroughly and unhurriedly; all findings are discussed in detail with patients and they are encouraged to raise questions about any problems. This is particularly important at the time of the initial diagnostic study. Patients frequently complain that the doctor does not discuss his findings with them or give them a chance to ask any questions. Another factor of importance is the encouragement given to patients to discuss emotional problems and the explanation to the patients, where appropriate, of the basis for symptoms in the absence of organic disease and the relationship of symptoms to emotional tension.

The above discussion, obviously written in the vernacular, was intended only as a personal record of the orientation talk with all new patients. The suggestion that it was worthy of publication was made by a member of the editorial staff of *MINNESOTA MEDICINE* who was aware of the type of practice that I carry out.

Several factors may be of additional interest. My practice is restricted to people who will accept this type of program. Over the years the amount of early asymptomatic potentially curable malignancy, particularly colon, cervix uteri, breast, thyroid, skin etc. that has been found is impressive.

HEALTH CARE IN A DOCTOR'S OFFICE

This is in addition to the not infrequent findings of previously undiagnosed hypertension, diabetes, chronic urinary tract infections, prostatic hyperrophy, early glaucoma, early cataracts etc. From his experience, the invariable question of justification on the basis of "yield" has been more than adequately answered. At the conclusion of the initial diagnostic study, a common comment from the patient is "This is the first time I have ever had a thorough exam." This experience plus an opportunity to discuss emotional problems which I routinely encourage is the basis for good rapport with patients resulting in an excellent doctor-patient relationship.

The following procedures are routinely carried out at the time of the initial diagnostic study and are repeated annually: complete history and physical examination with detailed report, chest fluoroscopy, six foot chest film, complete blood count, serial electrocardiograms (Masters test), sigmoidoscopic examination, sedimentation rate, icterus

index, urinalysis, Kahn test, stool occult blood, tonometer examination, Papanicolaou vaginal smears (females), multiphasic chemistry survey. In addition all patients over the age of 40 are advised to have a large bowel Xray periodically by a radiologist.

Another unusual feature of this health program is the fact that it is carried out on an annual flat-fee basis (not prepayment as the patient is allowed to budget the total cost over the entire year). The fee includes the initial diagnostic study and the follow-up exam at six months, all office calls and all office service provided during the year. I have never practiced on a fee-for-service basis for office care.

This approach to health care provides a comprehensive basis for 'primary care.' It is best carried out by an internist with broad rather than sub-specialty interest. All other necessary care should be ancillary care by the appropriate specialist under the direction of the personal physician.

Sixth Annual North Memorial OB-Gyn Symposium

On Friday, November 30, 1973, in Minneapolis, Minnesota, the Sixth Annual North Memorial Hospital OB-Gyn Symposium will be held. Selected speakers will discuss current topics of interest in our field. The Symposium will be followed the next day by the annual meeting of the Minnesota State Obstetrics and Gynecological Society. Inquiries should be directed to Alec Janes, M.D., Program Chairman, 601 Oakdale Medical Center, Mpls (55422).

In Memoriam

JOHN F. BILTZ, M.D.

Dr. John F. Biltz, 36, a radiologist on the staff of St. John's Hospital in Red Wing, was killed June 13, when his airplane crashed in a clover field near Prescott, Wisconsin. He was a graduate of the University of Minnesota Medical School.

Dr. Biltz was a member of the Radiological Society of North America, American Medical Association, Society of Air Force Internists and Allied Specialists, Bavarian-American Radiological Society, Minnesota State Medical Association and the Goodhue County Medical Society.

He is survived by his wife, Hannelore Helene, and three children.

JAMES W. REID, M.D.

Dr. James Reid, 54, South St. Paul physician, died June 17, while attending the Alaska State Veterans of Foreign Wars Convention at Sitka. He was a former national surgeon general of the Veterans of Foreign Wars.

Dr. Reid was a member of the Wakota County Medical Society, the American Medical Association and the Minnesota State Medical Association.

He is survived by his wife, Lota Jane, daughter, Mary, and sons, James, Phillip, Gregory and David.

IRA C. SKINNER, III, M.D.

Dr. Ira Skinner, 32, service member of the Minnesota State Medical Association, died February 23. He was a resident member of the Zumbro Valley Medical Society and the American Medical Association. At the time of his death, Dr. Skinner was in San Antonio, Texas.

CLIFFORD A. BOLINE, M.D.

Dr. C. A. Boline, 69, Battle Lake physician, died June 10, in Brownsville, Texas. He opened a general practice in Battle Lake in November, 1933, and served that community since that time. A graduate of the University of Minnesota Medical School, he interned at

the Charles T. Miller Hospital in St. Paul.

Dr. Boline was a former surgeon for the Northern Pacific Railway Company, a staff member of Wrights Memorial Hospital in Fergus Falls, and a member of the Park Region Medical Society, the American Medical Association and the Minnesota State Medical Association.

He is survived by his wife, Blanche and three sons, Alan, John and Robert.

WERNER J. LUND, M.D.

Dr. W. J. Lund, Staples physician and surgeon for the past 41 years, died June 28. He was 79 years of age.

His pre-medical schooling was taken at Loyola University in Chicago. While attending medical school at the University of Minnesota, he served as superintendent of the Northern Pacific Hospital in Brainerd. In 1932, he was transferred to Staples by the Northern Pacific Railway Company where he served as line surgeon and physician for the Railroad and the community.

He was a member of the Minnesota State Medical Association, the Upper Mississippi Medical Society, the American Medical Association and the National Association of Railway Surgeons.

Dr. Lund is survived by his wife, Myrtle and two daughters, Mrs. Phyllis Clabots and Miss Gloria Lund.

GRANT F. HARTNAGEL, M.D.

Dr. Grant F. Hartnagel, 63, Red Wing physician, died June 24. A graduate of the University of Minnesota Medical School, he took his internship at Milwaukee County Hospital, later returning to Red Wing to practice.

Dr. Hartnagel was certified by the American Board of Obstetrics and Gynecology and was a member of the Minnesota State Medical Association, the American Medical Association, the Minnesota Society of Obstetrics and Gynecology, the Goodhue County Medical Society and was a Fellow of the American College of Surgeons.

His wife, Elizabeth, and two daughters, Mrs. Thomas Sinkula and Jane Hartnagel, survive him.

Rodger R. Lundblad, M.D.

OCTOBER, 1973

Section 1 of Two Sections

Everybody experiences psychic tension.

Most people can handle this tension.

Some people develop excessive psychic tension and need your counseling,

and a few may need counseling
and the psychotropic action of Valium® (diazepam).

Before deciding to make Valium (diazepam) part of your treatment plan, check on whether or not the patient is presently taking drugs and, if so, what his response has been. Along with the medical and social history, this information can help you determine initial dosage, the possibility of side effects and the ultimate prospects of success or failure.

While Valium can be a most helpful adjunct to your counseling, it should be prescribed only as long as excessive psychic tension persists and should be discontinued when you decide it has accomplished its therapeutic task. In general, when dosage guidelines are followed, Valium is well tolerated (see Dosage). For convenience it is available in 2-mg, 5-mg and 10-mg tablets.

Drowsiness, fatigue and ataxia have been the most commonly reported side effects.

Until response is determined, patients receiving Valium should be cautioned against engaging in hazardous occupations requiring complete mental alertness, such as driving or operating machinery.

Before prescribing, please consult complete product information, a summary of which follows:

Indications: Tension and anxiety states; somatic complaints which are concomitants of emotional factors; psychoneurotic states manifested by tension, anxiety, apprehension, fatigue, depressive symptoms or agitation; symptomatic relief of acute agitation, tremor, delirium tremens and hallucinosis due to acute alcohol withdrawal; adjunctively in skeletal muscle spasm due to reflex spasm to local pathology, spasticity caused by upper motor neuron disorders, athetosis, stiff-man syndrome, convulsive disorders (not for sole therapy).

Contraindicated: Known hypersensitivity to the drug. Children under 6 months of age. Acute narrow angle glaucoma; may be used in patients with open angle glaucoma who are receiving appropriate therapy.

Warnings: Not of value in psychotic patients. Caution against hazardous occupations requiring complete mental alertness. When used adjunctively in convulsive disorders, possibility of increase in frequency and/or severity of grand mal seizures may require increased dosage of standard anti-convulsant medication; abrupt withdrawal may be associated with temporary increase in frequency and/or severity of seizures. Advise against simultaneous ingestion of alcohol and other CNS depressants. Withdrawal symptoms (similar to those with barbiturates and alcohol) have occurred following abrupt discontinuance (convulsions, tremor, abdominal and muscle cramps, vomiting and sweating). Keep addiction-prone individuals under careful surveillance because of their predisposition to habituation and dependence. In pregnancy, lactation or women of childbearing age, weigh potential benefit against possible hazard.

Precautions: If combined with other psychotropics or anticonvulsants, consider carefully pharmacology of agents employed; drugs such as phenothiazines, narcotics, barbiturates, MAO inhibitors and other antidepressants may potentiate its action. Usual precautions indicated in patients severely depressed, or with latent depression, or with suicidal tendencies. Observe usual precautions in impaired renal or hepatic function. Limit dosage to smallest effective amount in elderly and debilitated to preclude ataxia or oversedation.

Side Effects: Drowsiness, confusion, diplopia, hypotension, changes in libido, nausea, fatigue, depression, dysarthria, jaundice, skin rash, ataxia, constipation, headache, incontinence, changes in salivation, slurred speech, tremor, vertigo, urinary retention, blurred vision. Paradoxical reactions such as acute hyperexcited states, anxiety, hallucinations, increased muscle spasticity, insomnia, rage, sleep disturbances, stimulation have been reported; should these occur, discontinue drug. Isolated reports of neutropenia, jaundice; periodic blood counts and liver function tests advisable during long-term therapy.

Dosage: Individualize for maximum beneficial effect.

Adults: Tension, anxiety and psychoneurotic states, 2 to 10 mg b.i.d. to q.i.d.; alcoholism, 10 mg t.i.d. or q.i.d. in first 24 hours, then 5 mg t.i.d. or q.i.d. as needed; adjunctively in skeletal muscle spasm, 2 to 10 mg t.i.d. or q.i.d.; adjunctively in convulsive disorders, 2 to 10 mg b.i.d. to q.i.d. **Geriatric or debilitated patients:** 2 to 2½ mg, 1 or 2 times daily initially, increasing as needed and tolerated. (See Precautions.) **Children:** 1 to 2½ mg t.i.d. or q.i.d. initially, increasing as needed and tolerated (not for use under 6 months).

Supplied: Valium® (diazepam) Tablets, 2 mg, 5 mg and 10 mg; bottles of 100 and 500. All strengths also available in Tel-E-Dose® packages of 1000.

acute arthritic inflammation...heat that freezes

In acute rheumatoid arthritis consider Tandearyl. The anti-inflammatory action of Tandearyl quickly helps reduce heat, pain, swelling, and stiffness. Results are usually seen in 3 or 4 days. Try it for a week when the symptoms defy aspirin control.

Remember that Tandearyl is not a simple analgesic. It should not be used in patients responding to routine therapy. Before using, please read the prescribing information. It's summarized below.

Tandearyl® helps take the heat off phenylbutazone NF Geigy

tablets of 100 mg.

Important Note: This drug is not a simple analgesic. Do not administer casually. Carefully evaluate patients before starting treatment and keep them under close supervision. Obtain a detailed history, and complete physical and laboratory examination (complete blood count, urinalysis, etc.) before prescribing and at frequent intervals thereafter. Carefully select patients, avoiding those responsive to routine measures, contraindicated patients, and those who cannot be observed frequently. In patients not to exceed recommended dosage. Short-term relief of severe symptoms with the smallest possible dosage is the goal of therapy. Dosage should be taken with meals and a full glass of milk. Patients should discontinue the drug and report immediately any signs of fever, sore throat, oral lesions (symptoms of blood dyscrasia); dyspepsia, epigastric pain, symptoms of anemia, black or tarry stools or other evidence of intestinal ulceration or hemorrhage, skin reactions, significant weight gain or edema. A one-week trial period is adequate. Discontinue in the absence of a favorable response. Restrict treatment periods to one week in patients over sixty.

Indications: Acute gouty arthritis, rheumatoid arthritis, rheumatoid spondylitis.

Contraindications: Children 14 years or less; while patients; history or symptoms of G.I. inflammation or ulceration including severe, recurrent or persistent dyspepsia; history or onset of drug allergy; blood dyscrasias; renal, hepatic or cardiac dysfunction; hypersensitivity; thyroid disease; systemic edema; dermatitis and salivary gland enlargement due to drug; polymyalgia rheumatica and temporal arteritis; patients receiving other potent antirheumatic agents, or long-term antithrombotic therapy.

Warnings: Age, weight, dosage, duration of therapy, existence of concomitant diseases, concurrent potent chemotherapy affect incidence of toxic reactions. Carefully instruct and observe the individual patient, especially the aging (forty years and over) who have increased susceptibility to the toxicity of the drug. Use lowest effective dosage. Weigh the unpredictable benefits against po-

tential risk of severe, even fatal, reactions.

The disease condition itself is unaltered by the drug. Use with caution in first trimester of pregnancy and in nursing mothers. Drug may appear in cord blood and breast milk. Serious, even fatal, blood dyscrasias, including aplastic anemia, may occur suddenly despite regular hemograms, and may become manifest days or weeks after cessation of drug. Any significant change in total white count, relative decrease in granulocytes, appearance of immature forms, or fall in hematocrit should signal immediate cessation of therapy and complete hematologic investigation. Unexplained bleeding involving CNS, adrenals, and G.I. tract has occurred. The drug may potentiate action of insulin, sulfonylurea, and sulfonamide-type agents. Carefully observe patients taking these agents. Nontoxic and toxic goiters and myxedema have been reported (the drug reduces iodine uptake by the thyroid). Blurred vision can be a significant toxic symptom worthy of a complete ophthalmological examination. Swelling of ankles or face in patients under sixty may be prevented by reducing dosage. If edema occurs in patients over sixty, discontinue drug.

Precautions: The following should be accomplished at regular intervals: Careful detailed history for disease being treated and detection of earliest signs of adverse reactions; complete physical examination including check of patient's weight; complete weekly (especially for the aging) or an every two week blood check; pertinent laboratory studies. Caution patients about participating in activities requiring alertness and coordination, as driving a car, etc. Cases of leukemia have been reported in patients with a history of short- and long-term therapy. The majority of these patients were over forty. Remember that arthritic-type pains can be the presenting symptom of leukemia.

Adverse Reactions: This is a potent drug; its misuse can lead to serious results. Review detailed information before beginning therapy. Ulcerative esophagitis, acute and reactivated gastric and duodenal ulcer with perforation and hemorrhage, ulceration and perforation of large bowel, occult G.I. bleeding with anemia,

gastritis, epigastric pain, hematemesis, dyspepsia, nausea, vomiting and diarrhea, abdominal distention, agranulocytosis, aplastic anemia, hemolytic anemia, anemia due to blood loss including occult G.I. bleeding, thrombocytopenia, pancytopenia, leukemia, leukopenia, bone marrow depression, sodium and chloride retention, water retention and edema, plasma dilution, respiratory alkalosis, metabolic acidosis, fatal and nonfatal hepatitis (cholestasis may or may not be prominent), petechiae, purpura without thrombocytopenia, toxic pruritus, erythema nodosum, erythema multiforme, Stevens-Johnson syndrome, Lyell's syndrome (toxic necrotizing epidermolysis), exfoliative dermatitis, serum sickness, hypersensitivity angitis (polyarteritis), anaphylactic shock, urticaria, arthralgia, fever, rashes (all allergic reactions require prompt and permanent withdrawal of the drug), proteinuria, hematuria, oliguria, anuria, renal failure with azotemia, glomerulonephritis, acute tubular necrosis, nephrotic syndrome, bilateral renal cortical necrosis, renal stones, ureteral obstruction with uric acid crystals due to uricosuric action of drug, impaired renal function, cardiac decompensation, hypertension, pericarditis, diffuse interstitial myocarditis with muscle necrosis, perivascular granulomata, aggravation of temporal arteritis in patients with polymyalgia rheumatica, optic neuritis, blurred vision, retinal hemorrhage, toxic amblyopia, retinal detachment, hearing loss, hyperglycemia, thyroid hyperplasia, toxic goiter, association of hyperthyroidism and hypothyroidism (causal relationship not established), agitation, confusional states, lethargy; CNS reactions associated with overdosage, including convulsions, euphoria, psychosis, depression, headaches, hallucinations, giddiness, vertigo, coma, hyperventilation, insomnia; ulcerative stomatitis, salivary gland enlargement. (B)98-146-800-F (10/71)

For complete details, including dosage, please see full prescribing information.

More than sleep

your choice of sleep medication
is wisely based on more than
sleep-inducing potential

sleep with relative safety

Chronic tolerance studies have confirmed the relative safety of (flurazepam HCl); no depression of cardiac or respiratory was noted in patients administered recommended or high for as long as 90 consecutive nights.

In most instances when adverse reactions were reported, they were mild, infrequent and seldom required discontinuance of therapy. Morning "hang-over" with Dalmane has been relatively infrequent. Drowsiness, lightheadedness and the like have been the side effects noted most frequently, particularly in the elderly and debilitated. (An initial dose of Dalmane 15 mg should be prescribed for these patients.)

sleep for 7 to 8 hours
without need to
repeat dosage

No sleep medication has been as rigorously evaluated in the sleep research laboratory as Dalmane. Insomnia patients given one 30-mg capsule of Dalmane at bedtime, on average: fell asleep within 17 minutes, had few awakenings, spent less time awake after sleep onset, and slept for 7 to 8 hours with no need for repeat dosage during the night.

leep with
sistency

enane (flurazepam HCl) is a distinctive sleep medication—a benzepine specifically indicated for insomnia. It is not a barbiturate or methaqualone, nor is it related chemically to any other hypnotic.

When your evaluation of insomnia indicates the need for a sleep medication, consider Dalmane—a single entity nonnarcotic, non-habit-forming agent proved effective and relatively safe for relief of insomnia.

Dalmane has been shown to be consistently effective even during consecutive nights of administration, with no need to increase dosage.

DALMANE[®]

(flurazepam HCl)

When restful sleep is indicated

One 30-mg capsule h.s. — usual adult dosage
(15 mg may suffice in some patients).

One 15-mg capsule h.s. — initial dosage for elderly or debilitated patients.

Before prescribing Dalmane (flurazepam HCl), please consult Complete Product Information, a summary of which follows:

Indications: Effective in all types of insomnia characterized by difficulty in falling asleep, frequent nocturnal awakenings and/or early morning awakening; in patients with recurring insomnia or poor sleeping habits; and in acute or chronic medical situations requiring restful sleep. Since insomnia is often transient and intermittent, prolonged administration is generally not necessary or recommended.

Contraindications: Known hypersensitivity to flurazepam HCl.

Warnings: Caution patients about possible combined effects with alcohol and other CNS depressants. Caution against hazardous occupations requiring complete mental alertness (e.g., operating machinery, driving). Use in women who are or may become pregnant only when potential benefits have been weighed against possible hazards. Not recommended for use in persons under 15 years of age. Though physical and psychological dependence have not been reported on recommended doses, use caution in administering to addiction-prone individuals or those who might increase dosage.

Precautions: In elderly and debilitated, initial dosage should be limited to 15 mg to preclude oversedation, dizziness and/or ataxia. If combined with other drugs having hypnotic or CNS-depressant effects, consider potential additive effects. Employ usual precautions in patients who are severely depressed, or with latent depression or suicidal tendencies. Periodic blood counts and liver and kidney function tests are advised during repeated therapy. Observe usual precautions in presence of impaired renal or hepatic function.

Adverse Reactions: Dizziness, drowsiness, lightheadedness, staggering, ataxia and falling have occurred, particularly in elderly or debilitated patients. Severe sedation, lethargy, disorientation and coma, probably indicative of drug intolerance or overdose, have been reported. Also reported were headache, heartburn, upset stomach, nausea, vomiting, diarrhea, constipation, GI pain, nervousness, talkativeness, apprehension, irritability, weakness, palpitations, chest pains, body and joint pains and GU complaints. There have also been rare occurrences of sweating, flushes, difficulty in focusing, blurred vision, burning eyes, faintness, hypotension, shortness of breath, pruritus, skin rash, dry mouth, bitter taste, excessive salivation, anorexia, euphoria, depression, slurred speech, confusion, restlessness, hallucinations, and elevated SGOT, SGPT, total and direct bilirubins and alkaline phosphatase. Paradoxical reactions, e.g., excitement, stimulation and hyperactivity, have also been reported in rare instances.

Dosage: Individualize for maximum beneficial effect. *Adults:* 30 mg usual dosage, 15 mg may suffice in some patients. *Elderly or debilitated patients:* 15 mg initially until response is determined.

Supplied: Capsules containing 15 mg or 30 mg flurazepam HCl.

Opinion & Dialogue

"Prescription drugs – who should determine the maker?"

Dispenser of Medicine

Clifton J. Latiolais
President
American
Pharmaceutical
Association

Maker of Medicine

C. Joseph Stetler
President
Pharmaceutical
Manufacturers
Association

"Too many doctors are dependent to the economic consequences of their decisions." So stated an issue of *Medical News Report* (December 4, 1972), an independent weekly newsletter published by AMA Chief Executive F. J. L. game, M.D.

Doctor, are you indifferent...

In discussing an anticipated increase in Blue Shield rates, *Blue Shield* magazine's newsletter had this to say: "In general, it can be said that we have given the impression that we are not particularly concerned with the increase in cost of health care to patients..."

"True, an MD's training is primarily scientific, but in the real world of practice, all of his scientific decisions have a price tag, or an economic impact. The economics of health care beckon the practitioner's attention. Concern for economics of medicine..."

When the pharmacist recommends that a drug product other than the one ordered be dispensed, the prescriber invariably permits the change when he feels the best interests of the patient will be served.

Shortcomings of Pro-Substitution Argument

The fact remains that it is necessary for the prescriber to know when the change is being contemplated and to be in a position to consent or demur. Without that opportunity, a unilateral decision of the pharmacist, made in the absence of clinical knowledge of the patient, could expose to needless risks, and in addition, jeopardize the relationship between the professions of Pharmacy and Medicine. In my view, there is nothing in the pro-substitution argument that offsets these risks.

The Issue of Drug Knowledge

Substitution advocates claim that the primary justification for changing the rules is the desire to better utilize pharmacists' knowledge about drugs. Yet the pharmacist's task to keep current on the entire field of drug therapy, to some extent, puts him at a disadvantage. Most often, a practicing physician with his expert knowledge of no more than

be an obligation of medical societies...
 Medical societies ought to continue campaigns to point out substantial savings that could be realized thru deductible insurance protection for catastrophic illnesses. At the very least, they should, in the patients' interest, question the role of any insurance organization that raises health care costs by forcing policyholders to buy insurance they may not need or want and probably won't ever use.
 Too many doctors are indifferent to the economic consequences of their decisions. Too many, for example, habitually hospitalize patients for the convenience of the MD. It's easy to deny such habits exist...
 Doctors, thru their medical societies, have unhesitatingly appealed to patients for support in the fight against government interference in the private practice of medicine. The public in the past has responded. It's time the American Medical Association and state and local medical societies paid off the debt by their action to hold down the cost of health care."

Drugs
 Insurance rates and hospital charges are only two factors in health

care costs. The cost of drugs—both prescription and nonprescription—is another.

And when it comes to drug costs, the nation's pharmacists are concerned. Through their national professional society, the American Pharmaceutical Association, pharmacists are advising the public to use nonprescription medication cautiously and conservatively, and to seek the advice of their pharmacist before selecting or purchasing such drugs.

Outdated Laws

The pharmacist also is aware that when it comes to prescription drugs, often he has an even greater opportunity to reduce the cost to the patient—with no sacrifice in the quality of the medication dispensed. But in many states, outdated and antiquated laws prevent the pharmacist from engaging in drug product selection. "Drug product selection" simply means that the pharmacist functions in the patient's interest by consciously choosing, from the multiple brands available, a low-cost quality brand of the specific drug to be dispensed in response to the physician's prescription order.

Much *misinformation* has been purposely spread by those who stand to gain financially by maintaining

high drug costs to the public. An endless stream of propaganda has emanated from the drug industry in an effort to persuade the medical profession that these so-called anti-substitution laws should be retained. And as long as these laws are retained, the drug industry will continue its current marketing practices which contribute unnecessarily to high drug costs to patients. These practices also are inviting government agencies to expand their restrictive controls on physicians and pharmacists.

APhA Efforts

As pharmacists, we are concerned about health care costs. We hope that every physician shares our concern on this vital issue, and will give his personal support to the constructive efforts APhA has undertaken in the interest of all patients.

(For a complete discussion of drug product selection, you are invited to request a free copy of the "White Paper on the Pharmacist's Role in Product Selection" from: American Pharmaceutical Association, 2215 Constitution Avenue, N.W., Washington, D.C. 20037.)

ugs that he selects to treat the only of conditions encountered in practice. Moreover, the physician's choice of a specific brand is based on his knowledge of the product's medical history and current reputation, and his experiences with the particular manufacturer's product.
 Some substitution proponents have argued that the dispensing of a drug is a simple two-party transaction between the pharmacist and the patient, and that a substitution by the pharmacist may avoid even a minimal breach of contract by simply informing the patient that he is making a substitution. I would judge that such arguments would be sympathetic to a pharmacist who substituted without physician approval and who took a legal defense that seeks to make the patient responsible for the pharmacist's actions.

Prescription Prices?

Substitution advocates are appealing to the consumer, and particularly the consumer activist, that reduced prescription prices could be a result of legalization of substitution. We have seen absolutely no evidence to support this claim. To the contrary, experience in Alberta, Canada, where substitution is authorized, suggests

the opposite.

Many pharmacists understandably are concerned about the cost of maintaining multiple stocks of similar products. While there is no doubt that inventory costs rise when additional brands are stocked, it would be interesting to know how much they rise, and how many pharmacists actually stock *all* brands—of, say, ampicillin or tetracycline—or how long they keep "slow moving" products on their shelves before they are returned for credit. To ask that the industry eliminate multiple sources is to ask competitors to stop competing.

Drug Substitution—A License for the Unethical

Anti-substitution repeal would favor "corner cutting" pharmacists and manufacturers. For them, free substitution would be not a right, but a license. As an aftermath, it is quite likely that the confidence of both physicians and patients in the profession of Pharmacy would be eroded, as revelations about the unconscionable behavior of an undisciplined few were magnified in the press or in professional circles.

Summary

In short, what the American Pharmaceutical Association advo-

cates as a broad-spectrum panacea looks to us to be not only a minority view (advocacy of substitution is by no means a uniform policy in Pharmacy), but also an extraordinarily costly and ineffective remedy, whose side effects are odious. We believe (1) that an impressive majority of pharmacists prefer to work with Medicine and with industry, for the consumer, and for the general good, (2) that they seek the privilege to substitute when the patient might gain and when the patient's doctor agrees, and (3) that they seek to work for the resolution of genuine grievances openly and professionally.

(For amplification of PMA views, please write for our booklet, "The Medications Physicians Prescribe: Who Shall Determine the Source?" It is available from: Pharmaceutical Manufacturers Association, 1155 Fifteenth Street, N.W., Washington, D.C. 20005.)

ROCHE announces new

BACTRIMTM

Each tablet contains 80 mg trimethoprim and 400 mg sulfamethoxazole.

a new type of antibacterial for a two-pronged attack against chronic urinary tract infections due to susceptible organisms

Bactrim is highly effective in the treatment of these infections—primarily pyelonephritis, pyelitis and cystitis—when due to susceptible organisms. This efficacy is related to the unique mode of action against bacteria (see illustration), an action that, in effect, makes Bactrim a new type of antibacterial.

Bactrim interrupts the life cycle of susceptible bacteria

Unique mode of action interrupts the life cycle at two important points, thereby impeding the production of nucleic acids and proteins essential to these bacteria. These consecutive interruptions occur because sulfamethoxazole and trimethoprim resemble naturally existing substrates. By competitive replacement of these substrates, they inhibit further synthesis.

new **BACTRIM**TM

Each tablet contains 80 mg trimethoprim and 400 mg sulfamethoxazole.

for chronic urinary tract infections

Before prescribing, please see complete product information on last page of advertisement.

Excellent clinical response in chronic urinary tract infections even with obstructive complications

A multiclinic, double-blind study* of response to a ten-day course of therapy in 471† patients with chronic urinary tract infections demonstrated the superiority of Bactrim. On the 10th day after initiation of therapy, 91.7% (of 168 patients) showed significant bacteriological response to Bactrim, compared with 81.2% (of 144 patients) to trimethoprim and 64.5% (of 155 patients) to sulfamethoxazole. More than half of these patients had obstructive complications.

Excellent response maintained

Bactrim proved equally impressive in maintaining this bacteriological response. In the above study, after a ten-day course of therapy with Bactrim, 68.4% of patients with chronic urinary tract infections *maintained* response for up to 42 consecutive days, compared with 59.7% with trimethoprim and 44.4% with sulfamethoxazole. These results are particularly noteworthy considering the number of patients with obstructive complications—cases regarded as being notoriously difficult to treat.

Prescribing considerations

Clinical Limitations: Currently, the increasing frequency of resistant organisms is a limitation on the usefulness of all antibacterial agents, especially in the treatment of chronic and recurrent urinary tract infections. Not recommended for children under twelve.

Contraindications: Hypersensitivity to trimethoprim or sulfonamides. Pregnancy and during the nursing period.

Warnings and Precautions: Both sulfamethoxazole and trimethoprim have been reported to interfere with hematopoiesis. Complete blood counts should be done frequently. If a significant reduction in the count of any formed blood element is noted, Bactrim should be discontinued. Bactrim should be given with caution to patients with impaired renal or hepatic function, possible folate deficiency, severe allergy or bronchial asthma. Maintain adequate fluid intake. Urinalyses with careful microscopic examination and renal function tests should be performed during therapy, particularly for those patients with impaired renal function.

Adverse Effects: Among the most common side effects are nausea, vomiting, rash, leukopenia and elevations in SGOT and creatinine.

Usual adult dosage: two tablets every twelve hours for 10 to 14 days; no loading dose required.

*Data on file, Hoffmann-La Roche Inc., Nutley, N.J. 07110

†4 patients not available for evaluation at day 10.

new **BACTRIM**TM

Each tablet contains 80 mg trimethoprim and 400 mg sulfamethoxazole.

for chronic urinary tract infections

Roche Laboratories
Division of Hoffmann-La Roche Inc.
Nutley, N.J. 07110

Product Information:

Indication: Bactrim is a synthetic antibacterial combination product available in scored light-green tablets, each containing 80 mg trimethoprim and 400 mg sulfamethoxazole.

Chemical: Trimethoprim is 2,4-diamino-5-(3,4,5-trimethoxybenzyl) pyrimidine. It is a white to light-yellow, odorless, bitter compound with a molecular weight of 290.3.

Sulfamethoxazole: is *N*-(5-methyl-3-isoxazolyl)sulfanilamide. It is a white to light-yellow, odorless, tasteless compound with a molecular weight of 253.28.

Microbiology: Sulfamethoxazole inhibits bacterial synthesis of dihydrofolic acid by competing with *para*-aminobenzoic acid. Trimethoprim blocks the production of tetrahydrofolic acid from dihydrofolic acid by binding to and reversibly inhibiting the required enzyme, dihydrofolate reductase. Thus, Bactrim blocks two consecutive steps in the biosynthesis of nucleic acids and proteins essential to many bacteria.

Resistance: Studies have shown that bacterial resistance develops more slowly with Bactrim than with trimethoprim or sulfamethoxazole alone.

Spectrum: Serial dilution tests have shown that the spectrum of antibacterial activity of Bactrim includes the common urinary tract pathogens with the exception of *Pseudomonas aeruginosa*. The following organisms are usually susceptible: *Escherichia coli*, *Klebsiella-Enterobacter*, *Proteus mirabilis* and indole-positive proteus species.

Representative Minimum Inhibitory Concentration Values for Bactrim-Susceptible Organisms
(MIC—mcg/ml)

	Trimethoprim alone	Sulfamethoxazole alone	TMP/SMX (1:20) TMP	SMX
<i>Escherichia coli</i>	0.05—1.5	1.0 —245	0.05—0.5	0.95— 9.5
<i>Staphylococcus spp.</i>	0.5 —5.0	7.35 —300	0.05—1.5	0.95—28.5
<i>Streptococcus spp.</i>	0.5 —1.5	7.35 — 30	0.05—0.15	0.95— 2.85
<i>Enterobacteriaceae</i>	0.15—5.0	0.735—245	0.05—1.5	0.95—28.5

Pharmacology: Bactrim is rapidly absorbed following oral administration. The blood levels of trimethoprim and sulfamethoxazole are similar to those achieved when each component is given alone. Peak blood levels for the individual components occur one to two hours after oral administration. The half-lives of sulfamethoxazole and trimethoprim, 10 and 16 hours respectively, are relatively the same regardless of whether these compounds are administered as individual components or as Bactrim. Detectable levels of trimethoprim and sulfamethoxazole are present in the blood 4 hours after drug administration. Free sulfamethoxazole and trimethoprim blood levels are proportionately dose-dependent. After repeated administration, the steady-state ratio of trimethoprim to sulfamethoxazole levels in the blood is about 1:20.

Protein Binding: Sulfamethoxazole exists in the blood as free, conjugated and protein-bound forms; trimethoprim is present as free, protein-bound and protein-bound forms. The free forms are considered to be the biologically active forms. Approximately 44 percent of trimethoprim and 70 percent of sulfamethoxazole are protein-bound in the blood. The presence of 10 mg percent sulfamethoxazole in plasma does not influence the protein binding of trimethoprim. The protein binding of trimethoprim does not influence the protein binding of sulfamethoxazole.

Excretion: Excretion of Bactrim is chiefly by the kidneys through both glomerular filtration and tubular secretion. Urine concentrations of both sulfamethoxazole and trimethoprim are considerably higher than plasma concentrations in the blood. When administered together as Bactrim, neither sulfamethoxazole nor trimethoprim affects the urinary excretion pattern of the other.

Indications: Chronic urinary tract infections (primarily pyelonephritis and cystitis) due to susceptible organisms (usually *Escherichia coli*, *Klebsiella-Enterobacter*, *Proteus mirabilis*, and, less frequently, indole-positive proteus species).

Contraindications: Currently, the increasing frequency of resistant organisms limits the usefulness of all antibacterial agents, especially for the treatment of chronic and recurrent urinary tract infections.

Warnings: Hypersensitivity to trimethoprim or sulfonamides. Caution during the nursing period (see Reproduction section).

Adverse Reactions: Deaths associated with the administration of sulfonamides have been reported from hypersensitivity reactions, agranulocytosis, aplastic anemia and other blood dyscrasias. Experience with trimethoprim alone is much more limited, but it has been reported that there was hematopoiesis in occasional patients. In elderly patients concurrently receiving certain diuretics, primarily thiazides, an increased incidence of thrombopenia with purpura has been reported.

The presence of clinical signs such as sore throat, fever, pallor, purpura or jaundice may be early indications of serious blood disorders. Complete blood counts should be done frequently in patients receiving Bactrim. If a significant reduction in the count of any formed blood element is noted, Bactrim should be discontinued.

At the present time, there is insufficient clinical information on the use of Bactrim in infants and children under 12 years of age to recommend its use.

Precautions: Bactrim should be given with caution to patients with impaired renal or hepatic function, to those with possible folate deficiency and to those with severe allergy or bronchial asthma. In glucose-6-phosphate dehydrogenase-deficient individuals, hemolysis may occur. This reaction is frequently dose-related. Adequate fluid intake must be maintained in order to prevent crystalluria and stone formation. Urinalyses with careful microscopic examination and renal function tests should be performed during therapy, particularly for those patients with impaired renal function.

Adverse Reactions: For completeness, all major reactions to sulfonamides and to trimethoprim are included below, even though they may not have been reported with Bactrim.

Blood dyscrasias: Agranulocytosis, aplastic anemia, megaloblastic anemia, thrombopenia, leukopenia, hemolytic anemia, purpura, hypoprothrombinemia and methemoglobinemia.

Allergic reactions: Erythema multiforme, Stevens-Johnson syndrome, generalized skin eruptions, epidermal necrolysis, urticaria, serum sickness, pruritus, exfoliative dermatitis, anaphylactoid reactions, periorbital edema, conjunctival and scleral injection, photosensitization, arthralgia and allergic myocarditis.

Gastrointestinal reactions: Glossitis, stomatitis, nausea, emesis, abdominal pains, hepatitis, diarrhea and pancreatitis.

C.N.S. reactions: Headache, peripheral neuritis, mental depression, convulsions, ataxia, hallucinations, tinnitus, vertigo, insomnia, apathy, fatigue, muscle weakness and nervousness.

Miscellaneous reactions: Drug fever, chills, and toxic nephrosis with oliguria and anuria. Periarthritis nodosa and L. E. phenomenon have occurred.

The sulfonamides bear certain chemical similarities to some goitrogens, diuretics (acetazolamide and the thiazides) and oral hypoglycemic agents. Goiter production, diuresis and hypoglycemia have occurred rarely in patients receiving sulfonamides. Cross-sensitivity may exist with these agents. Rats appear to be especially susceptible to the goitrogenic effects of sulfonamides, and long-term administration has produced thyroid malignancies in the species.

Dosage and Administration: Not recommended for use in children under 12 years of age.

The usual adult dosage is two tablets every 12 hours for 10 to 14 days.

For patients with renal impairment:

Creatinine Clearance (ml/min)	Recommended Dosage Regimen
Above 30	Usual standard regimen
15-30	2 tablets every 24 hours
Below 15	Use not recommended

How Supplied: Tablets, containing 80 mg trimethoprim and 400 mg sulfamethoxazole—bottles of 100 and 500; Tel-E-Dose® packages of 1000; Prescription Paks of 40, available singly and in trays of 10. Imprint on tablets: ROCHE 50.

Reproduction Studies: In rats, doses of 533 mg/kg sulfamethoxazole or 200 mg/kg trimethoprim produced teratological effects manifested mainly as cleft palates. The highest dose which did not cause cleft palates in rats was 512 mg/kg sulfamethoxazole or 192 mg/kg trimethoprim when administered separately. In two studies in rats, no teratology was observed when 512 mg/kg of sulfamethoxazole was used in combination with 128 mg/kg of trimethoprim. However, in one study, cleft palates were observed in one litter out of 9 when 355 mg/kg of sulfamethoxazole was used in combination with 88 mg/kg of trimethoprim.

In rabbits, trimethoprim administered by intubation from days 8 to 16 of pregnancy at dosages up to 500 mg/kg resulted in higher incidences of dead and resorbed fetuses, particularly at 500 mg/kg. However, there were no significant drug-related teratological effects.

BACTRIMTM

Each tablet contains 80 mg trimethoprim and 400 mg sulfamethoxazole.

For over a quarter of a century, Blue Shield has been working with physicians. And listening to physicians. Together, we've helped promote efficient use of medical services in Minnesota. And developed more efficient ways to provide health care. This impressive tradition of working closely with you, the physician, is now continuing into our second quarter of a century as we reach out to help more Minnesotans than ever before.

President's Letter

ON AUGUST 1, 1973, HOUSE FILE 286 and Senate file 384 became if not the law of the land at least the law of our beautiful Minnesota. House and Senate files 286 and 384 are also known as "The Patient's Bill of Rights." It requires hospitals and nursing homes to hand each patient a piece of paper on which are inscribed those rights which we learned about long ago at our mother's knee, from our father's discipline and later from the admonitions of our teachers, friends and families. We call this code, "good manners" or "common courtesy" or "being polite." In ordinary relationships it is the essence of socialization. In a health care setting, it is the doctor-patient relationship. In the words of Leo Alexander* "The patient and his doctor trusting each other, forming with solidarity an alliance against illness."

Such things as privacy, confidentiality, courtesy and mutual respect all derive from man's humanity rather than from legislative edict. Where in our state are such rules of good manners violated that the legislature must insure them by law? Are we unable to carry out the ancient precepts of our forebears and teachers.

Perhaps at times we have all observed violations of good conduct. One of the disheartening experiences of my youth was to observe the decline of common courtesy within the military system. Some men who in civilian life had been the soul of courtesy somehow in the military underwent a deterioration of their humanity, and developed a cavalier attitude toward such things as privacy, confidentiality and respect. I keenly remember the crudity of pre-embarkation preparations at good old Camp Parks just over the hills from Berkeley, California. Those GI's were herded into a huge open gymnasium-like room, their clothes removed, their privacy impaled on the sword of military necessity and, naked, fearful, and sweating, were pushed through what was euphemistically called a physical examination. I believe the record was 1500 men in one six-hour period. That day ended with the auditorium filled with the acrid smell of frightened sailors and weary, disheartened, and disillusioned medical officers. Fortunately that sort of discourtesy was

not universal and even in the military many a civilian turned sailor struggled to apply comity and dignity to his dealings with patients.

Our civilian efforts in which we exercise some manner of control are quite different. The doctor-patient relationship is attended by mutual respect, courtesy, diligence and dignity. The Patient's Bill of Rights is superfluous in our system for we have long since learned that in an atmosphere of decorum and confidentiality and especially in an atmosphere of open communication, good medical care is the rule. Are some patients' rights violated? In some ways the system does discriminate against him. Where, for example, is the privacy of person when a clerk at the office reads the insurance report containing much that is personal. Where is the confidentiality when the superintendent of schools or the sales manager or the shop foreman is privy to all sorts of details of his employee's illness? Where is the dignity when an agency of government insists on minute details of diagnosis and treatment purportedly to authorize payment and where is respect when at times payment is retrospectively denied. Soon pre-admission authorization will be the way of doing business. Shades of Big Brother! Is this a system which guarantees dignity and insures humanity, or is it rather a system which erodes the very rights Senate file 384 has set out to protect—a system in which third parties be they employers or insurance carriers or government agencies intrude into a private relationship. And what about the doctor who is forced to participate in this destruction of dignity. Will he be able to continue in the face of such grossness to be the protecting and benevolent figure needed at times of illness? What can he do to protect himself from the degrading influence of such basic discourtesy. Perhaps what we need is a Bill of Rights for Physicians, a bill of rights to guarantee the physician an opportunity to treat his patient with the kind of respect each patient deserves.

Flexible Fiberoptic Bronchoscopy

SAMUEL E. STUBBS, M.D.* and EDWARD C. ROSENOW III, M.D.*

THE DEVELOPMENT OF the flexible fiberoptic bronchoscope (FFB) with a remote-controlled tip marked the beginning of a new era in the diagnosis and treatment of pulmonary disease. Following the discovery those small fiberglass threads arranged in a precise bundle—even in a flexed position—could transmit light and relay an image, the application of this principle to endoscopy significantly extended the range of visibility obtainable with conventional rigid instruments. Although reports of the development of semiflexible instruments for use in gastroscopic procedures appeared as early as 1936,¹ the first practical flexible bronchoscopes did not become available in this country until 1968 when Ikeda et al.,² working with the Machida Endoscope Co., Ltd., and Olympus Optical Co., Ltd., in Japan, pioneered the development of flexible fiberoptic bronchoscopy and its application to pulmonary endoscopic procedures.²

In 1969 we began using the FFB at the Mayo Clinic and, currently, we find it applicable in approximately 50% of our bronchoscopic procedures. In 1972 we used it in approximately 500 examinations. Although the conventional rigid bronchoscope is still important in both diagnostic and therapeutic bronchoscopy, we believe that the FFB can be an important addition to a well-organized and well-equipped endoscopy service.

Indications and Advantages

Indications

Common indications for diagnostic bronchoscopic examination are listed in the Table. With some exceptions the indications for use of the FFB are similar to those for the rigid bronchoscope. Therapeutic bronchoscopy appears to impose the greatest number of limitations on the use of the FFB.

Foreign bodies, with perhaps the rare exception of a straight pin, cannot be removed from the tracheobronchial tree by means of the FFB.

*Mayo Clinic and Mayo Foundation, Rochester, Minnesota.
See editorial, page 869.

Dilation of tracheobronchial strictures and trans-bronchoscopic lung biopsy also are not possible with the FFB.³

In cases of hemorrhage, Sackner et al.,⁴ stated that they could control bleeding by cold saline lavage and topical application of epinephrine. However, in cases of definite bleeding, we have been reluctant to use the FFB without rigid bronchoscopy. Profuse bleeding may be difficult to control, suctioning through the small channel of the flexible bronchoscope may be ineffective, and blood may obscure vision with the FFB. Hence, when bleeding is a major problem or when we anticipate obtaining a biopsy specimen from a lesion that appears to be vascular, we prefer the rigid bronchoscope. Obviously vascular structures are preferably not biopsied.

The aspiration of mucous plugs and retained secretions is often effective treatment of post-operative atelectasis and the removal of secretions prior to bronchography may permit a better quality of roentgenograms. Wanner and associates⁵ found that use of the FFB in conjunction with saline lavage was effective in the aspiration of thick, retained secretions. Our experience has been that most often such secretions can be removed most readily by direct aspiration through the rigid bronchoscope. The principal limitation to success with the FFB is the small channel through which secretions can be aspirated.

TABLE

Indications for Diagnostic Bronchoscopy

Persistent cough
Hemoptysis
Stridor
Localized wheezing
Abnormal thoracic roentgenogram
Abnormal sputum cytology
Pleural effusion
Diaphragmatic paralysis
Vocal cord paralysis
Diffuse parenchymal lung disease (with lung biopsy)
Bronchiectasis
Foreign body in bronchi
Mediastinal lesions
Brushing of peripheral lesions
Metastasis from unknown primary tumor
Upper esophageal lesions

In the management of lung abscesses that do not drain spontaneously into the tracheobronchial tree, bronchoscopy with the rigid bronchoscope is an accepted therapeutic procedure. An aspirating tip can be introduced through the bronchoscope to facilitate drainage if necessary. Currently, our experience with the FFB for this purpose is too limited to permit us to give a firm opinion.

Advantages

Despite the limitations to its use, the FFB has distinct advantages over the rigid bronchoscope. The major contribution of the FFB to endoscopy is an extension of the range of visibility, especially in the upper lobes. The flexible remote-controlled tip permits the instrument to be inserted sufficiently far to allow the bronchoscopist to see within the subsegmental bronchi. The depth of insertion is often limited only by the size of the instrument, permitting adequate inspection despite significant distortion, displacement, or stenosis of the bronchi.

Other reasons for the increasing popularity of use of the flexible bronchoscope are the lack of discomfort for the patient and its tolerance even by very ill patients. There is no need to hyperextend the neck and little or no possibility of endotracheal perforation. It is sometimes necessary to repeat bronchoscopy in patients examined initially by rigid instruments; in such an eventuality, any reluctance of patients to undergo another procedure frequently can be overcome by choosing the flexible instrument for the second examination.

Method of Bronchoscopy

Equipment

We use three different bronchoscopes. The FFB we use most often, the Olympus BF-5B, is illustrated in Figure 1. Its main features are a working length of 55 cm and a diameter of 5 mm,

an arc of flexion of the distal end of $+130^\circ$ to -30° , and a channel 1.5 mm in diameter through which local anesthetics and lavage solutions can be instilled or secretions aspirated. The light bundle is illuminated by a halogen cold-light supply (model CLE). An abrasive brush on a flexible wire can be inserted when brush biopsies are required. Another bronchoscope, the Olympus BF-5B2, has a working channel 1.76 mm in diameter through which delicate flexible forceps can be passed for biopsy of lesions under direct vision. The third instrument, manufactured by the Machida Endoscope Co., Ltd., has an additional feature which permits rotation of the distal tip in addition to flexion and extension. All of these instruments can be equipped with cameras for still or motion photography or for the transmission of closed-circuit television.

The bronchoscopes are sterilized cold by means of a combination of mechanical cleaning with a brush for the channel (supplied by the manufacturer) and use of 2% PVP-I (Betadine) solution. Lens cleaner, containing antifogging ingredients is applied to the objective lens and gently removed with gauze.

Preparation of the Patient

Currently, all examinations except those done at the patient's bedside are done in endoscopy rooms located near the operating rooms. Many patients are examined as outpatients and they do not stay in the hospital overnight. Any patient whose examination requires general anesthesia is kept overnight for observation.

The meal immediately prior to the procedure is withheld. For premedication, commonly meperidine (50 mg) and atropine (0.6 mg) are given by intramuscular injection before the patient goes to the endoscopy room. Dosages may vary depending on the clinical status of the patient or evidence of drug hypersensitivity.

Fig. 1—Flexible fiberoptic bronchoscope (Olympus BF-5B).

(From Rosenow, EC 111, Hughes, RW Jr.: Progress in bronchoesophageal endoscopy. Surg Clin 53:775, 1973. By permission of W. B. Saunders Company.)

For topical anesthesia, Cetacaine (Cetylite Industries, Inc.) is sprayed over the oropharynx, epiglottis, and larynx. With the patient's tongue held extended, two or three one-second applications are usually all that are required. Then, five ml of 4% lidocaine solution are instilled into the trachea with a syringe and curved metal cannula; for this part of the procedure, the patient holds his tongue extended and a laryngeal mirror is used for indirect visualization as the lidocaine solution is dripped first on and then through the vocal cords. Topical anesthesia is then complete.

The use of a good technique and avoidance of haste in the preparation of the patient allow the patient to be comfortable and obviate the need for excessive amounts of topical anesthetic to prevent coughing during the subsequent examination.

Application of local anesthetic by means of an ultrasonic nebulizer also may be an effective method of anesthetizing the entire respiratory tract.⁶

The patient is then led or taken by a cart to the examining table, where he is placed in a comfortable supine position. A restraint may be placed across the legs to prevent accidental falls from the table. The patient's eyes are then protected by gauze pads and a towel secured with towel clips. If sedation is necessary, diazepam, which has been shown to be an excellent premedication for bronchoscopic procedures,⁷ may be injected intravenously if the endoscopist thinks that desirable. We do not use it routinely, but find it helpful in long examinations or with anxious patients.

Insertion of Bronchoscope

The endoscopist may use one of several techniques

for insertion of the FFB. First, it can be passed through the rigid bronchoscope. For example, the results of conventional bronchoscopy may be negative in a patient with sputum that is positive for malignant cells. The FFB can then be inserted through the rigid instrument and, in some cases, successfully used to enable the bronchoscopist to see a small lesion that is beyond the range of the bronchoscope-telescope system. When a lesion is seen it can be biopsied, brushed, or curetted for histologic or cytologic study. Bronchial washings can also be obtained for cytologic study or appropriate cultures.

Second, the FFB can be inserted through an oral endotracheal tube; repeated withdrawal and introduction of the FFB is well-tolerated by patients. Bronchoscopy can be performed with the patient seated or supine, as an outpatient procedure, or at the bedside of an ill patient. Similarly, the FFB can be inserted through a tracheostomy tube or tracheostomy stoma.

Third, the FFB can be inserted through the transnasal route.⁸ This may be a convenient approach if examination only is necessary, but it is less suitable if repeated entry and withdrawal are required. We prefer to withdraw the FFB after brushing and to remove the brush from the distal end of the working channel in order to make smears from the brush. This avoids the dislodging of material that would occur if the brush were pulled through the working channel from the proximal end of the FFB. The FFB also may have to be withdrawn for cleaning the tip. Each reinsertion by way of the transnasal route would require passage of the bronchoscope through the vocal cords under direct vision.

Fig. 2—Uncuffed endotracheal tube with integral wire spiral.

(From Rosenow, EC III, Hughes, RW Jr.: *Progress in bronchoesophageal endoscopy*. Surg Clin 53:775, 1973. By permission of W. B. Saunders Company.)

Insertion through Endotracheal Tube

Most examinations are performed using a soft rubber, integral wire spiral, uncuffed endotracheal tube (Figure 2). The FFB is lubricated with clear lidocaine jelly and the endotracheal tube is threaded over the full working length of the FFB to the proximal end. The patient may then be asked to hold an oval plastic mouth guard between the teeth or gums as an additional safeguard to prevent damage to the bronchoscope's delicate fiberglass bundles. The patient can then be approached from either side or from the head, depending on the preference of the endoscopist. The lights are dimmed and the tip of the FFB is passed behind the tongue and epiglottis and through the vocal cords into the trachea under direct vision. At this time, the appearance of the larynx, vocal cords, and subglottic area can be examined and the mobility of the vocal cords determined.

Once the distal one-third of the FFB has passed into the trachea, the endotracheal tube is lubricated with lidocaine jelly and guided over the FFB into the trachea and secured with adhesive tape. Sometimes a gentle spiral or twisting motion of the endotracheal tube over the FFB is necessary in order to facilitate passage of the tube through the larynx and vocal cords. Infrequently, the endoscopist may choose to insert the endotracheal tube when the patient is prepared, using the laryngeal mirror for visualization of the vocal cords. We find that the former method is well accepted by the patient and easy to perform, and we thus prefer it to direct laryngoscopy for intubation or the transnasal approach. It is obvious that an endotracheal tube is not always necessary if the endoscopist wishes to perform a limited examination or, if withdrawal and reinsertion of the FFB are necessary, he does not mind repeatedly passing the instrument through the vocal cords into the trachea. There is an increased risk of damage to the fiberglass bundles, however, should the patient bite the instrument.

If supplemental oxygen is required, an adapter with a close-fitting perforated diaphragm and a side-arm for attachment of anesthesia equipment may be used. This adapter can be used effectively for the administration of general anesthesia, if desired.

Examination

With the endotracheal tube in place, the trach-

eobronchial tree can be examined carefully and unhurriedly. If additional anesthesia is required to control coughing, 0.5- to 1.0-ml doses of 4% lidocaine can be instilled through the working channel. Secretions can be aspirated directly or after lavage with five to 10 ml of sterile saline. If the aspirate is to be collected for culture or cytologic study, a trap bottle is used.

If lesions can be seen, delicate flexible forceps can be inserted for biopsy under direct vision or an abrasive brush can be swept onto the lesion to take smears for cytologic study. The brush can also be used to take material for culture. As the FFB is withdrawn following repeated brushings, additional lubrication of the scope with lidocaine jelly will facilitate reinsertion. Fluoroscopic guidance may be necessary for accuracy, particularly if peripheral, nonvisualized lesions are to be brushed. A good time to lavage and collect the aspirate for study would appear to be following the brushing of a lesion.

Other Applications of Flexible Fiberoptic Bronchoscopy

New applications of flexible fiberoptic bronchoscopy are constantly being developed. The FFB has been used for selective catheter placement for the purpose of bronchography, lobar lung lavage and gas sampling.⁴ It has been used in the study of patients with respiratory failure who require prolonged mechanical ventilation.^{9,10} The FFB has also been used in studying bacterial infection of the lower respiratory tract, special techniques of collection of secretions being made possible by use of this instrument.⁵

When smaller instruments become available more extensive examination of the peripheral bronchi will be possible. This may have an important impact on attempts to detect lung cancer at an early stage. We have used the FFB for esophagogastroscope in infants, since no infant gastroscope is available. A syringe filled with air can be used to insufflate air into the stomach for better visualization.

The FFB has permitted us to make bronchoscopic examinations of patients in whom examination is difficult or impossible with the rigid instruments, either because of anatomical abnormalities or cervical spine disorders that make hyperextension of the neck undesirable or impossible. By means of the technique that we have described the FFB can be used effectively in the intubation of patients for general anesthesia who otherwise

might require a tracheostomy because of a fractured cervical spine, ankylosed cervical spine, or some other abnormality. In this instance, use of the FFB permits application of the topical anesthetic before intubation while the patient is

awake and before general anesthesia is induced. A cuffed flexible endotracheal tube is threaded over the FFB, which acts as a guide. Recently, a smaller flexible fiberoptic instrument was developed especially for this purpose.¹¹

Gynecologic Laparoscopy

CARL E. JOHNSON, M.D.* and REGINALD A. SMITH, M.D.*

EVERY PHYSICIAN WHO includes gynecology in his practice has at times wished for an examination of the pelvis that was more accurate than the usual bimanual examination but less traumatic than laparotomy in establishing the presence or absence of pelvic disease when diagnosis was uncertain, yet urgent. In past years this need led to the use of pneumogynecography, hysterosalpingography, posterior colpotomy, and culdoscopy—all valuable aids to the gynecologist and aids that continue to be used regularly in selected cases. However, laparoscopy, or transabdominal peritoneoscopy, has transcended all other methods short of laparotomy for full visualization of the pelvic structures and has offered a method of minor pelvic surgery and tubal sterilization as well. All recent reports have expressed enthusiastic satisfaction with laparoscopy and its use has become widespread. Potential complications and problems secondary to pneumoperitoneum and anesthesia, however, present a risk to the patient, and the procedure should not be considered minor office surgery. Our patients are given a complete preoperative physical examination and laboratory study, which includes roentgenogram of the chest, hematology, urinalysis, blood grouping, and Rh determination.

Visualization of the human peritoneal cavity with a cystoscopelike instrument was first described in 1910 by Jacobaeus¹ in Stockholm. Peritoneoscopy has been used infrequently through the years, but with recent improvements in light source (fiber-optic cold light) and operating technique (controlled pneumoperitoneum with carbon dioxide) and with increasing sophistication of instruments for visualization and intra-abdominal manipulation, gynecologic laparoscopy has been used more widely.

Gynecologic laparoscopy was first started in the

Mayo Clinic in 1971, primarily for diagnostic problems. In 90% of our cases, however, it has since been used for elective tubal sterilization and in only 10% for diagnostic reasons. Many instruments are now available and will not be dealt with here, nor will the technique of establishing pneumoperitoneum and insertion of the laparoscope be described, as detailed information can be found in the medical literature.

Anyone planning to do laparoscopy would be well advised to gain instruction at one of the centers teaching this procedure or to work with a colleague who has received appropriate training. The procedure should be performed in an operating room so that immediate treatment for intra-abdominal bleeding, visceral injury, or abdominal wall hematoma may be undertaken. Accidents that may accompany pneumoperitoneum and anesthesia require the presence of an anesthesiologist.

Obesity contributes to difficulty, particularly in establishing pneumoperitoneum; however, it can occasionally be attained via the posterior vaginal fornix with the patient in deep Trendelenburg position. The presence of previous abdominal surgical incisions presents the possibility of adhesions limiting vision and, also, adherent loops of bowel that may be punctured when the trocar is inserted.

Diagnostic Use

Laparoscopy in clarifying questionable pelvic pathology is particularly valuable in the patient suffering chronic or acute pelvic pain with essentially negative findings on pelvic examination. Chronic pelvic inflammatory disease, or endometriosis, is not infrequently noted in such patients. When no pelvic pathologic condition is noted, this gives support to the probable functional basis of the patient's symptoms that can then be dealt with more realistically.

The differential diagnosis between ectopic pregnancy and corpus luteum of pregnancy can be clearly established; however, laparoscopy is not

*Department of Obstetrics and Gynecology, Mayo Clinic and Mayo Foundation, Rochester, Minnesota.
See editorial, page 871.

indicated if the findings on examination are likely to be due to ectopic pregnancy. Laparoscopy should not replace surgical exploration of the abdomen when indicated. It should never be used if intestinal obstruction is suspected or in the presence of acute peritonitis. The patient with acute pelvic inflammatory disease who inadvertently is exposed to laparoscopy should be treated with appropriate antibiotics. A pedunculated fibroid in the adnexal area may obviate exploration or ovarian tumor, particularly in the older patient.

At this clinic it has been the policy not to perform biopsy on smooth cystic or solid ovarian lesions that may harbor malignancy for fear of spreading cellular contents. Biopsy of excrescences or papillary projections on the surface of ovarian tumors for microscopic study can be accomplished easily. The patient with obvious abdominal carcinomatosis need not undergo exploration when the necessary biopsy of a peritoneal lesion is obtained by laparoscopy. If ascites is present, the fluid should be removed prior to pneumoperitoneum. Laparoscopy has been used by some as a "second-look procedure" after operation for malignancy. We have had no such experience.

Laparoscopy has been used in cases of infertility, particularly in patients in whom no abnormality has been detected by other studies. If laparoscopy is performed at the proper time in the menstrual cycle, ovarian evidence of ovulation, tubal patency, and endometrial biopsy can be determined at one time; small tubal adhesions can be cut and punctate areas of endometriosis

cauterized. Developmental anomalies such as uterine duplication, ovarian agenesis, and Stein-Leventhal ovaries are easily visualized, and biopsy of the ovary in patients having amenorrhea is possible. The intrauterine contraceptive device that has perforated the uterus and lies free in the pelvis can be removed by laparoscopy.

Tubal Sterilization

Partial bilateral tubal cautery and excision are easily accomplished. The tube must not be mistaken for round ligament or utero-ovarian ligament. Coagulation cautery is applied first and followed by cutting cautery until there is separation of the tubal ends, 1 to 2 cm from the fundus of the uterus. A small segment of tube is then removed for microscopic identification, although many do not think that removal of a portion of tube is necessary. Coagulation cautery is usually ample to correct bleeding. Postoperative salpingography is not done for fear of forcing open the successfully occluded tube. We have not employed laparoscopy sterilizations less than six weeks postpartum.

Reestablishment of tubal patency is possible in any type of tubal sterilization, and, for this reason, a positive result is not guaranteed. In a study² of 29,496 tubal sterilizations of all types, the failure rate was 0.7%. In other reports² of large series done by laparoscopy, the rate is considerably lower than this figure (0.3%).

Ectopic pregnancy may occur if tubal excision near the cornua is performed after ovulation has occurred and before a possible conceptus can

Fig. 1—A split-leg operating table, such as that used for vein-stripping operations, and apparatus used during laparoscopy.

reach the uterus. For this reason, we prefer performing tubal sterilization during or shortly after menses, or on patients taking contraceptives orally and faithfully until the date of operation. The patient who has uterine pathologic conditions, cystocele, or rectocele and requests sterilization is better managed by hysterectomy or vaginal hysterectomy and repair as indicated. Vasectomy is discussed with all couples and is usually recommended instead of laparoscopy-sterilization of the female. The decision rests with the patient and her husband.

Anesthesia

Patients undergoing laparoscopy are admitted

to the hospital the morning of operation and most are given general anesthesia consisting of thiopental (Pentothal) and succinylcholine (Anectine) intravenously and halothane (Fluothane) by inhalation. These patients are intubated and respiration is controlled by the anesthetist. Atropine is usually given before operation but otherwise there is no preparation such as shaving, catheterization, or enema. (Enemas may lead to undesirable gas distention of the colon.) Abdominal and vaginal preparation with soap and Merthiolate is done after anesthetization. These patients are hospitalized for six hours or overnight after the procedure.

Fig. 2—Uterine cannula and cervical tenaculum in place allowing movement of the uterus from below as illustrated.

Fig. 3—Position of personnel during operation.

A number of patients are given intravenous doses of diazepam (Valium) and alphaprodine (Nisentil) accompanied by abdominal local block. Intubation is not necessary and the patient is released from the recovery room after one or two hours. No problems with acid-base shift have been encountered because the procedure takes only 10 to 12 minutes and the carbon dioxide is then expressed from the abdomen. The trocar sites are closed with subcutaneous catgut unless bleeding requires suture hemostasis.

We have found the operating table used for

vein stripping to be useful for laparoscopy because it avoids the necessity of putting the patient's legs in stirrups (Figure 1, 2, and 3). The legs can be separated so that manipulation of the cervical tenaculum with the intrauterine probe is easily accomplished for uterine mobility when necessary. Dilatation and curettage also can be done with the patient in this position. Laparoscopy will continue to be an important diagnostic procedure. A simpler method of sterilization is desirable.

He loved to have the cloth laid, because it had been the fashion of his youth, but his conviction of suppers being very unwholesome made him rather sorry to see anything put on it; and while his hospitality would have welcomed his visitors to everything, his care for their health made him grieve that they would eat.

Such another small basin of thin gruel as his own was all that he could with thorough self-approbation, recommend; though he might constrain himself, while the ladies were comfortably clearing the nicer things, to say—

“Mrs. Bates, let me propose your venturing on one of these eggs. An egg boiled very soft is not unwholesome. Serle understands boiling an egg better than anybody. I would not recommend an egg boiled by anybody else—but you need not be afraid, they are very small, you see—one of our small eggs will not hurt you. Miss Bates, let Emma help you to a *little* bit of tart—a *very* little bit. Ours are all apple-tarts. You need not be afraid of unwholesome preserves here. I do not advise the custard. Mrs. Goddard, what say you to *half* a glass of wine? A *small* half-glass, put into a tumble of water?”*

Esophageal Findings in 755 Fiberoptic Upper Gastrointestinal Endoscopies

GERALD R. ONSTAD, M.D.*

THE PURPOSE of this paper is to define the relationship between patients' symptoms and the frequency and type of esophageal lesions. The records of all patients at Hennepin County General Hospital who underwent gastrointestinal endoscopy during the three-year period, 1970 through 1972, were reviewed.

Fiberoptic technology has developed to the stage where esophagus, stomach and duodenum can be easily examined. The trained physician will routinely visualize all three areas during endoscopy. Even though the data to be presented refer almost exclusively to the esophagus, it represents experience with both esophagogastroscope and esophagogastroduodenoscopy. Esophagoscopy as an isolated examination was rarely performed.

Results

During the three-year period, 1970 through 1972, 755 upper gastrointestinal endoscopies, using a forward viewing instrument, were performed. The average patient was 50 years with a range from 17 to 94. Males outnumbered females two to one. Other than mild sore throat, no complications were associated with these procedures. Approximately 2% of attempted endoscopies (16 patients) were unsuccessful.

Table 1 lists the indications for upper gastrointestinal endoscopy, the total number of procedures performed for each indication, and the frequency of abnormal esophageal findings. "Pain" in this table refers to non-specific upper abdominal distress and was almost always associated with negative upper gastrointestinal studies. "Xrays" refers to findings of barium studies which needed clarification and/or biopsy. To avoid duplication, "Followup" endoscopies are

not included in the remaining data. Almost all patients without esophageal lesions had endoscopic abnormalities in the stomach or duodenum.

Upper gastrointestinal bleeding, manifested by either hematemesis and/or melena, could be related to an esophageal lesion 30% of the time. Table 2 separates this bleeding group into alcoholic and non-alcoholic populations. If bleeding from esophageal varices is excluded, then similar numbers of patients from each group are bleeding from esophagitis and Mallory-Weiss tears. For the other indications listed in Table 1, the alcoholic population comprised about 20% of each total, and the frequency of different types of abnormal endoscopic findings was not disproportionate.

TABLE 1
Frequency of Esophageal Lesions Related to Indications for Endoscopy

Indication	Total Endoscoped	Esophageal Lesions Number	% of Total
Bleeding	333	99	30
Pain	111	16	14

Number in Population	155	178	333
% with Esophageal Lesion	44	17	30

*Director, Section of Gastroenterology Hennepin County General Hospital and Assistant Professor of Medicine, University of Minnesota Medical School.

From the Department of Medicine, Hennepin County General Hospital, Minneapolis, Minnesota, and the University of Minnesota Medical School.

Eighty-seven percent (288/333) of the bleeding group had radiographic barium studies of the upper gut. As might be anticipated, these X-ray studies did not demonstrate either esophagitis or a Mallory-Weiss tear. Varices were seen radiographically in 18, less than half of the 42 directly visualized through the endoscope. In this variceal group, an additional benefit of the barium study was the demonstration of lesions distal to the esophagus in 10%.

Endoscopy for indications other than bleeding showed esophageal lesions in about 25% (87/350). Esophagitis accounted for the majority of these lesions, about 80% (70/87). In decreasing order of frequency, esophageal cancer, esophageal rings, esophageal diverticula, and achalasia make up the remaining positive findings. Except for esophagitis, the barium studies in these patients accurately defined all lesions.

The radiographic diagnosis of hiatus hernia and its relationship to the endoscopic diagnosis of esophagitis is shown in Table 3. Overall, hiatus hernia was seen in about 10% of all barium studies done (71/638). Of all patients with endoscopic esophagitis, about 40% had coexistent roentgenographic hiatus hernia and conversely, about 60% of the patients with esophagitis had no hiatus hernia. Of those with hiatus hernia, about 65% had concomitant esophagitis.

TABLE 3
Relationship of Radiographic Hiatus Hernia
and Endoscopic Esophagitis

Radiographic Hiatus Hernia	Endo- scopic Present	Esopha- gitis Absent	% Esophagitis
Present (71)	46	25	65%
Absent (567)	63	504	11%
% Hiatus Hernia	42%	5%	

Biopsy through the endoscope was positive in seven cases of esophageal cancer and negative in one. Multiple pieces of tissue were obtained in all these cases and, on the average, one in six yielded tumor. One grossly benign-appearing stricture showed histologic cancer on biopsy. Histologic esophagitis was sometimes demonstrated in biopsies from grossly normal esophageal mucosa.

Discussion

Hennepin County General Hospital serves both the medically indigent and emergent patients of Hennepin County. On the average, more alcoholics and alcoholics with more advanced liver

disease are seen here than in a private hospital of similar size. If this alcoholic population is excluded from the above data, a significant number of the remaining patients (20-25%) had esophageal lesions associated with their symptoms that led to endoscopy. This non-alcoholic population should be similar to the group seen in other acute care hospitals.

In this hospital, the patient with upper gastrointestinal bleeding is endoscoped as soon as possible after admission and barium studies usually obtained within 48 hours. For the other categories listed in Table 1, barium studies almost always precede endoscopy. These X-ray studies help the clinician decide whether or not endoscopy might be helpful, and also, frequently indicate the area of abnormality. For both the radiologist and the endoscopist, knowing where to look should increase the useful information obtained from either procedure.

In previous years, a variety of complaints have been attributed to the presence of a hiatus hernia. Recent studies relating the function of the gastroesophageal sphincter, hernia, and esophagitis¹, and endoscopic studies relating hernia and esophagitis² indicate that symptoms are not due to the hiatus hernia per se. In this series, 65% of patients with hiatus hernia had coexistent esophagitis. This incidence is probably abnormally high since asymptomatic patients with hiatus hernias are usually not endoscoped. Over half the patients with esophagitis do not have a hiatus hernia.

At present, biopsies obtained through the fiberoptic endoscope are tiny. Specimens rarely show more than mucosa. Multiple biopsies must be obtained from suspicious lesions and are helpful only if positive. Negative biopsy does not exclude disease. If a deeper biopsy specimen is desired, some other method must be used. Cytologic examination of material obtained by washing, brushing, or scraping the esophageal mucosa is useful in some centers³ but is not done at this hospital.

In this series, no complications occurred as a result of endoscopy. However, perforation of the gut, bleeding, cardiac arrhythmias, and adverse reactions to drugs, as well as other undesirable events, have been reported.^{4,5,6} The procedure involves some risk and should be done only when clearly indicated. A trained endoscopist working with an informed, cooperative patient will minimize the generally accepted morbidity and mortality rate of 0.1 to 0.3%.^{4,5,6}

Summary

The relationship between symptoms and frequency and type of esophageal lesions found during upper gastrointestinal endoscopy in 755 patients is described. If esophageal varices are

excluded, the frequency of abnormal endoscopic findings is similar for alcoholic and non-alcoholic populations. As might be expected, esophagitis, with or without radiographic hiatus hernia, was the most frequent abnormality noted.

Applications of Endoscopy to the Visualization of Biliary and Pancreatic Ducts

J. A. VENNES, M.D.*

FIBEROPTIC ENDOSCOPY is becoming generally available as a safe, precise technique in evaluation of the upper gastrointestinal tract. Extension of endoscopy to include the difficult evaluation of possible biliary and pancreatic disease is an important recent advance. Initially developed in Japan,¹⁻³ experience and refinements of technique are now reported from other centers.⁴⁻⁶ General availability for endoscopists is anticipated within several years. This report describes the procedure and results of 192 studies. Representative clinical application is shown.

Methods

Patients were selected because a diagnostic problem was incompletely resolved after clinical evaluation with conventional measures. Clinical diagnoses are summarized in Tables 1 and 2.

The fasting patient is prepared with Diazepam (Valium) 2-30 mgm. for sedation. Dicyclomine HCl (Bentyl) 60 mgm. and Atropine Sulfate 0.6 mgm. are given intramuscularly initially to effect duodenal atony and ampullary smooth muscle relaxation. Alternatively, smaller amounts of anticholinergic drugs may be supplemented by intravenous Glucagon 0.5-1.0 mgm. at periodic intervals during the procedure.

Vennes, M.D., Gastroenterology Section, Veterans Administration Hospital, 54th & 48th Ave. South, Minneapolis, Minnesota 55417.

The procedure is carried out in a radiology examining room equipped with padded table and fluoroscopic monitor which provides an image of good resolution. A side-viewing flexible duodenoscope is gently passed through the stomach and duodenal bulb into the descending duodenum. After an expeditious search of the descending and proximal third portion of the duodenum, the papilla is identified and cannulated (Figures 1-2).

Sixty percent Diatrizoate (Renografin) is cautiously injected under close fluoroscopic control. If only the pancreatic duct is being opacified, 2-5 ml of dye are injected slowly to avoid ductal over-distension. If the common bile duct is entered 5-40 ml of contrast agent will be needed to fill all structures; the larger amounts are required if the gallbladder fills during the procedure. In visualizing the gallbladder or a dilated common bile duct the use of 20% Renografin is frequently advisable so that small filling defects are not overlooked. If the desired duct is not initially entered, the cannula is repositioned, and contrast agent again introduced into the other ductal system. The technical details of this maneuver have been largely mastered. Finally, spot films are quickly obtained as good ductal detail is defined fluoroscopically.

Results

Of 230 cannulation attempts, 196 were successful. More importantly, the clinically desired duct was visualized in diagnostic detail in 174 (75%). In our most recent experience, 91 of the last 100 cannulation attempts have visualized the clinically desired duct.

Experience in the study of patients with suspected pancreatic disease is summarized in Table 1. Detailed results in this group are being reported separately.⁷ The primary diagnosis of pancreatic carcinoma was erroneously interpreted as chronic pancreatitis in three patients, since the two diseases co-existed. Ductal disruption was part of the necrotizing process of pseudocyst for-

mation in all 10 alcoholic patients studied so that the cyst filled readily as the duct began filling. In two more non-alcoholic patients pseudocyst formation was evidenced by ductal obstruction. Ductal visualization four weeks after episodes of acute pancreatitis has not been greatly rewarding. Two unsuspected pseudocysts were visualized as two instances of calculi in the gallbladder and common duct were discovered. In a third patient an extremely large spastic papilla prevented duct

Fig. 3—Normal cholangiogram. Patient with recurrent acute pancreatitis was studied to rule out associated biliary tract disease. Pancreatic duct was outlined later in the study.

Fig. 4—Normal pancreatogram. Note distal end of fiberoptic endoscope in air-filled descending duodenum. Instrument diameter is 10 mm. Duct pursues a normal tapering course with many fine secondary lateral branches filled.

visualization and this patient has been treated with sphincteroplasty at another hospital. Though we have not recognized papillitis as a cause of pancreatitis, the longer term results in this patient are awaited with interest. The group of patients with chronic pancreatitis are being systematically studied to determine whether ductal characteristics

offer any pathogenetic clues. Ductal characteristics may also be helpful in planning the surgical approach occasionally needed in management. Tortuous dilatation, with or without obstruction and dilated snubbed off lateral branches are the most frequent findings in chronic pancreatitis. In six patients a normal retroperitoneal space was correctly interpreted from findings of normal pancreatic duct position. This aided in the evaluation of radiologically suspected retrogastric mass lesions.

The 108 patients studied because of suspected biliary tract disease are divided in two categories (Table 2). Thirty-eight studies were attempted because extrahepatic obstruction was of clinical concern in patients with presumptive primary liver disease as the cause of jaundice. Surgical cholangiography was obviated in this group of patients. Although only a few proved to have extrahepatic obstruction many had abnormalities of the intrahepatic biliary tree. The remaining 70 patients with a clinical diagnosis of extrahepatic obstruction were studied to determine the site and etiology of obstruction preoperatively. Surgical management was thus facilitated and shortened.

Endoscopic cholangiography proves to be highly specific in determining the existence, site and etiology of extrahepatic obstruction.⁸ Studies listed as failures in either the pancreatic or biliary system include those in which the clinically desired duct was not visualized either because of failure to cannulate the papilla or because only the other ductal system was visualized. In three patients an endoscopic diagnosis of malignancy in the ampullary area was made although cannulation was impossible. In four more patients complete ductal obstruction was found at surgical exploration. Most failures occurred in the developmental phases of the procedure.

Endoscopic cannulation is generally very easily tolerated by the patient. Seven patients developed pancreatitis as evidenced by abdominal pain of over two hours duration and elevated amylase levels; none had fever or leukocytosis. When urine amylase levels were determined within 24 hours after the procedure in a randomly selected group of 70 patients who experienced no post-procedural discomfort, we found hyperamylasuria in more than one third.⁹ This is similar to the experience of others.⁴ Febrile reactions developed 24 hours after the procedure in eight patients.

Fig. 5—Many gallstones in common duct and gallbladder. 65-year-old man with two weeks' history of vague RUQ pain. Serum bilirubin fell from nine to four mgm percent; alkaline phosphatase four x normal. No previous history of biliary tract disease. Pancreatic ducts were beginning to empty but normal when outlined earlier in study. Surgery expedited by study; initial surgical cholangiogram obviated.

Fig. 6—Pancreatic pseudocyst. 48-year-old alcoholic male presenting with persisting pain, fever, hyperamylasuria. Pancreatic calcification on abdominal X-ray. Note ductal filling in head of pancreas with (immediate) extravasation of dye into cyst-like space. Pseudocyst demonstrated, no attempt made to define its size. At surgery a layer cyst cavity was successfully drained through a cystgastrostomy.

Two of these occurred after dye entered a pancreatic pseudocyst and in the other six after visualizing an obstructed common bile duct. Three of the latter group had clinical evidence of cholangitis. These serious reactions have been avoided since adopting a policy of early surgery. When obstruction of either ductal system is clinically suspected the problem is reviewed with surgical colleagues and the patient is tentatively scheduled for surgical management the day following en-

doscopic study. In our opinion, this policy should be rather rigidly adhered to.

Conclusion

Fiberoptic endoscopy has been successfully adopted to the study of the pancreatic and biliary ducts. Visualization of the clinically desired system may be expected with acceptably high frequency, producing studies of diagnostic quality. Low morbidity can now be expected. The procedure can be learned by trained endoscopists with sufficient ease so that it is expected to become generally available.

Our development of this new procedure is due in large measure to the patient assistance and judgment of Marsha Dreyer and Helen Donahue. Their special dedication is gratefully acknowledged.

Sixth Annual North Memorial OB-Gyn Symposium

On Friday, November 30, 1973, in Minneapolis, Minnesota, the Sixth Annual North Memorial Hospital OB-Gyn Symposium will be held. Selected speakers will discuss current topics of interest in the field. The Symposium will be followed the next day by the annual meeting of the Minnesota State Obstetrics and Gynecological Society. Inquiries should be directed to Alec Janes, M.D., Program Chairman, 601 Oakdale Medical Center, Mpls (55422).

Removal of Gastric Polyps by Fiberoptic Gastroscope

PAUL B. DICKINSON, M.D.* and ALPHONSO A. BELSITO, M.D.*

SNARE-CAUTERY DEVICES have recently been designed for use through fiberoptic colonoscopes. Volf and Shinya have demonstrated that colon polyps can be removed safely and reliably by this method.¹ The following report describes successful removal of gastric polyps by using a similar snare-cautery device through the fiberoptic gastroscope.

Materials and Technique

The Olympus model GIF panendoscope was used to perform the polypectomies. It is of end-viewing design and has a working length of 100 cm. The snare-cautery device has a self-forming loop and can be operated with one hand (Figure 1).[†]

The procedure is performed in an endoscopic examining room in the outpatient department. Premedication with IM Meperidine and Atropine is administered 30 minutes prior to procedure. Diazepam is administered intravenously immediately prior to intubation. The esophagus, stomach, and duodenum are examined closely for presence and severity of atrophic mucosal changes. If possible, the patient is positioned so that the polyp is suspended into the gastric lumen (Figure 2).

We use the same technique for snaring and amputation of gastric polyps that we use for removal of colon polyps. A loop is formed, passed over the polyp and maneuvered near the base of the stalk (Figure 3). With the polyp under direct vision, current is applied to the snare and with

slow steady pressure the polyp is severed. The sheath with snare wire is immediately removed and suction is applied to impact the severed polyp in the tip of the gastroscope. The polyp can almost always be retrieved if constant suction is maintained while the gastroscope is removed. If this maneuver is unsuccessful the polyp can be grasped by the biopsy forceps and the gastroscope removed with forceps in place. The patient is then re-intubated and the stalk remnant closely examined. Any bleeding points present are fulgurated by electrocautery (Figure 4). After observation in the endoscopy area for two hours the patient is

Fig. 2—Antral polyp. A portion of the stalk is visible.

discharged home or to the ward. A soft diet is prescribed for seven days and the patients instructed to seek medical attention at once if hematemesis or melena occurs.

Clinical Experience

Fourteen pedunculated polyps were removed from 11 patients. Clinical data and endoscopic findings and diagnosis are presented in the Table. There was a high incidence (nine out of 11) of atrophic gastric mucosa. The two polyps which had malignant changes were both less than 2.0 cm. in diameter. The polyps with long stalks were technically more difficult to snare because they were more mobile. The procedure was well tolerated and post-polypectomy bleeding or perforation was not encountered.

Discussion

Approximately 50% of patients with gastric polyps are completely asymptomatic.² The most common presenting complaint is abdominal pain which in most cases is caused by an associated gastritis. Iron deficiency anemia is a common

finding. This anemia may be caused by repeated small hemorrhages from the polyps but in many cases is the result of impaired iron absorption because of the accompanying hypo and achlorhydria. As a general rule, the larger the polyp the more likely it will ulcerate and bleed but on occasion even a small adenoma may bleed profusely. Symptoms of intermittent outlet obstruction may accompany an antral adenoma with a long stalk that prolapses into the pyloric canal.

Gastric polyps are considerably less frequent than colon polyps. Marshak and Feldman found an incidence of 0.28% in 50,000 upper gastrointestinal barium studies and a mean incidence of 0.43% after review of 74,823 autopsies.² The incidence is much higher in selected populations such as individuals with hypochlorhydria (1.1%), achlorhydria (3.4%), and Addisonian pernicious anemia (6.5%).³

After gastric polyps are detected close surveillance is required because of their association with carcinoma of the stomach. Up to the present time the working approach towards gastric polyps has been to remove those greater than 2 cm. in diameter.

TABLE
Findings in Nine Patients with Gastric Polyps.

Age	Presenting complaint	Endoscopic findings	Diagnosis
62	Epigastric pain	15mm polyp on 10mm stalk in mid antrum	adenomatous polyp
73	none	8mm polyp on 10mm stalk in distal antrum, atrophy	adenomatous polyp
74	anemia	10mm polyp on 20mm stalk in mid antrum, gastric atrophy	adenomatous polyp
65	anemia	15 & 18mm polyp on long stalk in antrum gastric atrophy	2 adenomatous polyps
76	anemia	10mm polyp on 15mm stalk and 15mm polyp on 20mm stalk severe gastric atrophy	carcinoma in tip of both polyps
62	none	15mm polyp on 15mm stalk, gastric atrophy	adenomatous polyp
59	none	20mm polyp on 15mm stalk. Severe atrophic mucosa	adenomatous polyp
30	epigastric pain	Peutz-Jagher syndrome numerous small polyps. Two largest were 20 and 22mm	adenomatous polyp (x2)
72	none	18mm polyp in low body on 15mm stalk. Severe gastric atrophy	adenomatous polyp
66	anemia	15mm polyp in antrum on 10mm stalk, gastric atrophy	adenomatous polyp
73	epigastric pain	20mm polyp in low body, 10mm stalk, severe gastric atrophy	adenomatous polyp

ter because the risk of malignancy is considerable in a polyp of that size.⁴ The possibility of carcinoma occurring in an adenoma less than 2 cm. in diameter was recognized but the incidence was believed to be so low as to not justify the risk associated with surgical removal. That size alone is not an infallible criterion for absence of malignancy as emphasized by reports of carcinoma in small gastric polyps by Bowden,⁵ Rosato and Noto,⁶ Hay,⁴ and from the present series. A difference of opinion exists, regardless of polyp size, as to their malignant potential.^{7,8} Recently, Tomasulo has described criteria for subdivision of polyps into two histologic types, hyperplastic and adenomatous.⁹ The hyperplastic type of polyp was more numerous, was randomly distributed in the stomach, and was infrequently associated with gastric carcinoma. The adenomatous type of polyp was antral in location and associated frequently with achlorhydria, malignant transformation and infiltrative carcinoma. The two types of polyps had the same roentgenographic characteristics.

Endoscopic gastric polypectomy appears to be a low risk procedure without significant complication.¹⁰ It is well tolerated by elderly patients, many of whom have coexistent medical problems which place them at high risk for surgical polypectomy.

The ability to remove gastric polyps with the gastroscope will improve the management of patients with these gastric tumors. A precise diagnosis can be made with the entire polyp available for histologic examination. If adenomatous epithelium or carcinoma in situ is identified the patient should have segmental resection of a rim of uninvolved mucosa. Partial gastrectomy may be the treatment of choice if multiple polyps are present. Patients who have adenomatous polyps of the type associated with gastric carcinoma should have roentgenographic or endoscopic evaluation every 6 months. Management of gastric polyps in this fashion will lead to earlier detection of gastric carcinoma and increase the survival rate of patients with this type of neoplasm.

Polypectomy Using the Fiberoptic Colonoscope

CECIL H. CHALLY, M.D.* and WILLIAM D. BLACKWOOD, M.D.†

WITH THE ADVENT of colonoscopy, neoplasms beyond the reach of the sigmoidoscope can be directly evaluated. Now benign and malignant polyps can be observed, biopsied, and removed without laparotomy and colotomy with its inherent mortality of 0.4 to 2 percent^{1,2,4,5} and morbidity as high as 20 percent.¹⁻⁵

Sigmoidoscopic treatment of polyps is well established¹ and now colonoscopy allows adaption of this approach to removal of polyps from the rest of the colon. As a result of the pioneering work of Wolff and Shinya^{6,7} colonoscopic removal of polyps has become practical for the experienced endoscopist. In the recently published report of their experience with 303 polypectomies, the most encouraging aspect of their work was the low morbidity and lack of mortality. These data are supported by Ottenjann's work.⁸

This paper summarizes the Minneapolis V.A. Hospital experience over the past 10 months during which 58 polyps greater than 0.5 cm were removed with the colonoscope.

Methods

Patients were admitted to the hospital on the day prior to the procedure. A complete history and physical examination was done. Routine lab studies included a complete blood count, a platelet count, a prothrombin time, a chest Xray and an electrocardiogram.

Preparation for the procedure consisted of a three-day liquid diet, kanamycin 500 mg p.o. q.i.d. for two days, and bisacodyl NF 10 mg. p.o. or castor oil two ounces 24 hours prior to the

procedure. On the morning of the examination the patient received tap-water enemas until clear. Inadequate bowel cleansing on this regimen was unusual.

Just prior to the procedure, diazepam was given slowly intravenously to a state of mild sedation and 60 mg. dicyclomine HCL was given intramuscularly to decrease bowel motility. The dose of diazepam necessary for mild sedation varied from 1 to 20 mg. and must be given carefully in patients over 60 and in those with diminished pulmonary reserve. On this regimen the patient tolerated the procedure with only mild discomfort. Passage of the well-lubricated colonoscope was accomplished in the left lateral recumbent

position and the entire colon was examined using this or the supine position. After the polyp was located and biopsied, it was positioned properly in the bowel lumen. Then either of the wire snares (Figures 1 and 2) was placed over the polyp and the loop tightened around its base. The proximal end of the snare was attached to the electrosurgical unit[†] and the stalk or base of the polyp was transected with a coagulating current which provides hemostasis. Following excision we examined the site for bleeding. The resected polyp was retrieved by aspirating it into the tip of the colonoscope or by grasping it with the snare

Fig. 3—X-ray picture of representative polyp.

and then withdrawing the entire colonoscope. This sequence of events is depicted in Figures 3, 4, 5, 6 and 7.

Fig. 6—Polyp base after resection of the polyp with its stalk.

Fig. 7—Retrieved polyp of approximately 2.0 centimeters diameter.

The patient was observed for a change in his vital signs and colonic bleeding. If no complications occurred the patient was discharged the following day with instructions to notify us immediately if rectal bleeding occurred. One month later a barium enema was performed in an attempt to document removal of the polyp. If the polyp was sessile and at the time of resection not completely removed, colonoscopy was repeated six weeks later. Long-term follow-up includes a yearly proctosigmoidoscopy and barium enema.

Results

Fifty-eight polyps were removed from forty-seven patients. Three patients had two examinations in order to remove multiple polyps. The size of the polyps varied from 0.5 to 4.0 cm as shown in Table 1. Polyps under 5 mm in diameter were excluded from this study since they are very rarely malignant^{1,8,9} and are readily treated by biopsy and coagulation.

The distribution of the fifty-eight polyps is shown in Table 2. Seventy-three percent were located in the rectum and sigmoid colon. Localization of polyps in reference to anatomic divisions is more satisfactory than by distance from the anal verge since the sigmoid loop stretches or telescopes during the procedure.

While pedunculated polyps were readily re-

moved, sessile polyps often were difficult to snare especially if they were located between haustra. All the polyps were removed in toto and not piecemeal. Polyps which appeared malignant were biopsied and no attempt was made to remove them. The majority of the polyps removed were benign adenomas as is shown in Table 3. Distinction was made between "superficial" and "invasive" carcinomatous changes because of previous literature findings.^{3,9-14} Superficial carcinomas may be adequately treated by local excision, whereas

Total	58

invasive carcinoma should be treated by surgical resection.

Usually polyps could be removed at the first attempt, but occasionally, because of length of the procedure or technical difficulties, a second attempt was needed.

Complications

There were three immediate complications which occurred in the first twenty-five cases. Brisk bleeding occurred following the resection of one 2.0 by 4.0 cm sessile polyp and one 3.0 cm polyp with a 1.0 cm stalk. Total blood loss in each case was approximately 100 ml. The most serious complication was a bowel perforation which resulted in an emergency laparotomy with colostomy and later reanastomosis. An experimental snare (Frankenfeld) used for this procedure had a sharp, rigid tip especially when extended from the tubing a short way. Since that time three different snares* with tips, which are blunt and flexible, have been used without difficulty.

Discussion

With the advent of colonoscopy a procedure is now available which complements radiologic detection of colonic disease. In previous studies when the colon was examined using a sigmoidoscope inserted through multiple colotomy sites, 14

to 46 percent of the patients had polyps not shown by prior x-ray examination.^{2,5,9} In two studies 15 to 30 percent of these polyps were greater than 1.0 cm.^{2,9} Furthermore, grossly invasive carcinomas undetected by barium x-ray studies were also found using this technique.* Based on these findings, we therefore feel that the entire colon must be examined by colonoscopy prior to polypectomy.

Removal of polyps using the colonoscope appears to provide an acceptable alternative for laparotomy and colotomy. Colonoscopy is tolerated well by the patients, thus it is not difficult to obtain consent for a second or third procedure. The studies of Wolff and Shinya⁶ as well as the present one show that polyps can be removed via the colonoscope with no mortality and low morbidity. However, polyp removal can result in complications which require immediate surgical intervention. Thus sound medical and surgical evaluation prior to the procedure is necessary and adequate surgical backup must be readily available. Because of the remote possibility of emergency surgery, patients are given a standard surgical bowel preparation before polypectomy.

In our estimation, a physician who has experience in upper gastro-intestinal endoscopy, can acquire a high degree of proficiency in colonoscopy by performing about 50 examinations. The polypectomy technique can be mastered with moderate additional training time.

Excisional biopsy of the polyp allows complete histologic examination of the entire lesion which is impossible with simple biopsy through the

colonoscope. Therefore, when in situ, superficial, or invasive cancer is encountered, it can be dealt with correctly. As outlined in Welch's monograph,¹ in situ and superficial carcinomas can be treated effectively by polypectomy. If invasion of the muscularis mucosa has occurred a subsequent standard cancer procedure is done.^{3,9,10}

At the present time follow-up examinations include a yearly barium enema and proctosigmoidoscopy. Support for this type of follow-up is provided by the reports of Rider et al.¹⁵ and Deddish and Hertz.² Rider found that in 537 patients followed for four to nine years after polyp removal 40 percent developed additional benign polyps and 3.2 percent developed carcinomatous polyps or invasive cancer of the colon.

Since the average hospital stay for colonoscopic polypectomy is one to two days versus seven to ten days following laparotomy and colotomy, the cost of hospitalization will greatly decrease using this approach.¹⁶ The ability of the patient to return to work in a few days in contrast to several weeks delay after laparotomy also further eases his financial burden.

Whether removal of all polyps prevents later development of colonic carcinomas is still a matter of much debate.^{13,14,17} Polyps measuring 1.0 to 2.0 cm on barium enema have a 10 percent chance of being malignant, and above this size the incidence of cancer increases.^{1,8,9} The malignant polyps which we resected ranged from 1.0 to 4.0 cm in size. If the present mortality and morbidity figures continue to be representative of polyp removal, colonoscopy polypectomy should provide an attractive alternative to laparotomy.

Gastric Malignancy

Gastroscopic Experience

ALPHONSO A. BELSITO, M.D.* and PAUL B. DICKINSON, M.D.*

CARCINOMA OF THE STOMACH appears to be declining in incidence in the United States as opposed to other parts of the world. Nevertheless, it continues to be a significant cause of cancer deaths and poses difficulties in differentiation from benign gastric ulcer.

Malignant gastric lesions have been discovered in 58 patients out of more than 600 gastric ulcers examined in the past five years by esophagogastroduodenoscopy. The roles of fiberoptic endoscopy and upper-gastrointestinal roentgenogram were reviewed regarding the prompt and accurate evaluation of the patient with an intragastric lesion or ulcer. The influence of early diagnosis on subsequent treatment was also examined.

Method

The patients were examined in eight community hospitals. The endoscopic examination in nearly all instances followed the upper-gastrointestinal roentgenogram and was performed at the same hospital within one week.

The technique and premedication have been previously described.¹ Several different instruments were used for the examinations as the development of new, flexible, fiberoptic instruments has been rapid since 1967. Currently, we use the GIF[†] flexible fiberoptic esophagogastroduodenoscope as our routine instrument for examination of the upper-gastrointestinal tract. This is an end-viewing 100 cm. endoscope and has full biopsy, aspiration, washing and photographic capabilities from the esophagus into the second portion of the duodenum. Some of our examinations were performed using the JF-B side-viewing 120 cm. duodenoscope, although its primary use has been for cannulation of the Papilla of Vater with subsequent retrograde cholangiopancreatography.

Patients with a diagnosis of carcinoma of the stomach or malignant lymphoma have been reviewed. All appropriate roentgenographic reports were studied. A mention of malignancy, cancer, mass, rigidity or suspicious appearing ulcer or lesion was considered a positive roentgenographic diagnosis of malignancy.

A positive diagnosis of malignancy by endoscopy consisted of an endoscopic impression of possible malignant change being present or if the biopsy was positive for cancer despite a benign endoscopic impression.

Surgical protocols and pathology reports were reviewed in all cases to determine attempted curative resectability of the lesions. The patients discussed in this manuscript were examined between July, 1967, and March, 1973.

Results

A total of 58 cases of malignancy of the stomach have been reviewed. Fifty-two of these tumors were adenocarcinomas and the remainder were malignant lymphomas. This represents approximately 10% of the total number of ulcers we have examined endoscopically. All diagnoses were established by surgical exploration and biopsy except for four patients who refused surgery. Each of these four had far advanced, easily recognized carcinoma on barium meal and endoscopic examination. Three of these patients had positive gastroscopic biopsies of carcinoma while the fourth patient was examined at a time when gastroscopic biopsy capability was not available (GTF-A used.)

There were 30 men and 28 women. The patients' ages were from 36 to 91 years with an average age of 70 years. The average age was not different in any of the categories listed nor in the resectable lesions as opposed to the metastatic group. The four youngest patients of the entire group (36, 39, 46 and 51) all had far advanced, unresectable disease.

See editorial, page 870.

The symptoms were those typically ascribed to gastric pathology and consisted of pain, anorexia, weight loss and anemia. Forty-five of the patients had a chief complaint of pain with eating.

The criteria used to categorize patients regarding a positive roentgenographic or endoscopic diagnosis have been described in the methods section.

The patients were placed in the following groups:

- I. Positive diagnosis by Xray and endoscopy
- II. Normal or benign Xray diagnosis and malignant endoscopic diagnosis
- III. Delayed positive diagnosis by Xray, endoscopy or both
- IV. Missed diagnosis by Xray and endoscopy
- V. No Xray performed

I. Positive Diagnosis by Xray and Endoscopy
35 patients [63%]

This is the largest group of patients as one would expect. Thirty-five of 56 patients were diagnosed or suspected of malignant disease on the initial upper-gastrointestinal roentgenogram and endoscopic examination. In most instances a confirmatory endoscopic examination was promptly followed by surgical exploration. Four of the patients in this group had a malignant lymphoma.

Twenty-five of the 35 patients in this group had unresectable or widely metastatic disease present at the time of surgery (29% resectability). Seven of the remaining ten patients had disease localized to the stomach.

II. Normal or Benign Xray Diagnosis and Malignant Endoscopic Diagnosis
14 Patients [25%]

Fourteen patients with cancer had an UGI series with a benign ulcer described (nine) or the UGI series was simply interpreted as being normal (five). In each instance the endoscopic examination was either strongly suspicious of malignancy, and could not rule it out, or in one patient, a malignant biopsy was obtained from what appeared to be a benign ulcer not visualized on the x-ray examination. Nine of 13 biopsies in these 14 patients were positive for malignancy (one negative was lymphoma). Twelve of these 14 patients had resections performed (89%), although only two had negative nodes. Two patients had lymphoma, and both were localized, resectable disease.

Fig. 1—Irregular mucosa overlying an infiltrating carcinoma. Biopsy showed atypical cells but not diagnostic of carcinoma. Xray detected a superficial ulceration. Operated because of symptoms.

Fig. 2—Malignant ulcer with a prominent, irregular rolled edge. Endoscopic biopsy positive for malignancy. UGI showed the lesion was "penetrating" and not malignant.

Fig. 3—Malignant ulcer thought benign at surgery. UGI series and endoscopy could not exclude malignancy and endoscopic biopsy was positive. No extension to lymph nodes at surgery.

Fig. 4—Far advanced, obvious adenocarcinoma of the stomach.

III. Delayed Positive Diagnosis by Xray, Endoscopy or Both (five patients [11%])

Five patients were ultimately diagnosed as carcinoma but a delay from three months to one year ensued between the time of the initial examination to the time of diagnosis. Two of these patients had a positive endoscopic impression and biopsy on the first examination, but this had been preceded by observation for three months of a poor healing gastric ulcer that was finally considered suspicious for malignancy on barium meal examination.

Two of the remaining three patients had been initially examined with a viewing only gastroscope (GTF-A) and follow-up endoscopy (three months and one year respectively) showed apparent carcinoma and the biopsy was positive. The third patient with a delay in both Xray and endoscopy diagnosis showed a poor healing large ulcer over three months time. Carcinoma was suspected on the last upper GI series. Biopsy at repeat endoscopy was positive as opposed to an initially negative biopsy.

IV. Missed Diagnosis by Xray and Endoscopy (one patient [1%]) (Figure 1)

This was an 83-year-old male who 20 years earlier had a gastrojejunostomy and vagotomy performed for duodenal ulcer disease. Because of pain and vomiting, upper-gastrointestinal roentgenogram and endoscopy were performed. Both showed deformity, atrophy, and a patent stoma. Endoscopy revealed a polypoid lesion in the antrum and a small ulceration. Biopsy was benign. In view of his symptoms, he was operated shortly thereafter and found to have an infiltrating, submucosal carcinoma beneath the ulcerated antrum. One adjacent lymph node was positive for malignant spread.

V. No Xray performed (two patients)

There were two men (ages 91 and 71 years) who were diagnosed as advanced carcinoma of the stomach at endoscopy with positive biopsies. Neither had an x-ray examination. Neither was resectable.

Endoscopic Biopsy

Forty-one patients out of the total of 52 patients with carcinoma had endoscopic biopsies with one patient being biopsied on two separate occasions. Thus, a total of 42 biopsies in 41 patients were performed. The remaining 10 patients with carcinoma were examined prior to the

availability of fiberoptic gastroscopic biopsy instruments.

Thirty-five biopsies were positive for carcinoma (83%). The single repeat biopsy was positive on the second examination (patient cited in subgroup III above). In the majority of these cases the positive biopsy provided very useful information in that it confirmed, at times, equivocally positive Xray and endoscopic impressions. In several patients the biopsy occurred with negative or benign roentgenographic impressions and a doubtful endoscopic visual impression of cancer.

The six patients with lymphoma all had biopsies performed. Two were interpreted as positive for adenocarcinoma and the other four were called inflammatory reaction, predominantly lymphocytic in variety. One of the positive biopsies occurred in a patient with hemorrhage, a negative GI series and a large fundal ulcer with lymphoma localized to the stomach.

In our total endoscopic "biopsy" experience of several hundred, we have had two instances of a false positive biopsy for carcinoma. One occurred with a large, bleeding posterior wall ulcer and negative x-ray examination. The other contradicted a benign ulcer roentgenographic impression and equivocal endoscopic visual impression. Both patients had large, benign gastric ulcers at subsequent surgical resection.

Discussion

The patients who are the subject of this review assuredly do not represent a random selection of patients with gastric malignant ulcer. Each has been selected for endoscopic examination on the recommendation of a referring physician. In a high percentage of cases, the radiologist has suggested endoscopy for confirmation or clarification of a gastric lesion. These same selection factors operate in most gastroscopic examinations, as a minority of physicians routinely obtain endoscopy on patients with ulcers, other lesions or unexplained gastrointestinal symptoms.

Despite the uncontrolled selection factors, some interesting results are apparent. Namely, utilizing both upper-gastrointestinal roentgenography and fiberoptic endoscopic examinations, a very high degree of accuracy can be obtained in the diagnosis of gastric cancer. If one relies entirely on the x-ray examination, a significant percentage of false negative examinations (26%—Group II) and delayed diagnoses (11%—Group III) can

result. It is here that endoscopy with biopsy demonstrates its usefulness. Only two of these 21 patients (groups II and III), were not diagnosed on the initial gastroscopic examination when combined with biopsy of the ulcer. The one patient of these two "misses" was correctly diagnosed on a follow-up examination with biopsy, and the second patient underwent prompt surgery despite negative Xray and endoscopy because of his symptoms. These data are very similar to our earlier experience in which all diagnoses of ulcer, either benign or malignant were critically reviewed.¹

Perhaps the most significant fact to be demonstrated is that an earlier diagnosis of cancer of the stomach is clearly associated with an increased rate of resectability and presumably curability. If one examines the ulcers diagnosed by *both* Xray and endoscopy as malignant, the rate of curative resection was 29%. On the contrary, of those patients diagnosed as having malignant ulcer only by endoscopic examination (16 patients), 14 (87.5%) had a curative resection. Excluding lymphomatous lesions, 12 out of 14 carcinomas underwent curative resection. Certainly not all patients undergoing "curative resection" will be cured of their disease. If resection cannot be performed no cure is possible at all. Follow-up data must be accumulated to decide the true cure rate in these patients.

These findings are furthermore in agreement with those previously published both in this country and in Japan. Comfort et al.² reporting on 220 small malignant ulcers and over 700 benign ulcers at the Mayo Clinic found a 32 percent erroneous diagnosis of benign gastric ulcer in gastric carcinomas under four cm. in size. It was in this group that the higher five year survival rate (60%) was present as opposed to those lesions called gastric cancer on x-ray study (32% five year survival). The accuracy of upper-gastrointestinal roentgenogram in diagnosing malignant ulcer increased with the size of the ulcer, approaching 80% in lesions over three cm. size and 58% for lesions less than two cm. While two-thirds of the cancers were over three cm., it was difficult to diagnose, smaller than two cm. carcinomas that a 71% five year cure rate was achieved. Brown and Cain³ reviewed 106 incidental gastric cancers found at surgical resection for presumed poor healing gastric ulcer. Again

the five year survival rate was size related, being 89% for lesions less than one cm. in size and 43% for those of 3-6 cm. size. Kasugai⁴ and Prolla⁵ have reviewed the Japanese experience in gastric malignancy. In Japan, gastric carcinoma is the most common malignancy with an incidence of 70/100,000 in males and 38/100,000 in females. This contrasts with United States figures of 19/100,000 and 10/100,000 for male and female respectively.⁶ Despite differences in incidence, the resectability and cure rates for invasive carcinoma are very similar in the two countries, being 15% to 50% depending on the presence of nodal metastases.⁷ Over a 95% cure rate has been achieved when "early" carcinoma is found and treated in a conventional fashion.⁴

Thus the challenge to eradicate the high mortality of gastric carcinoma can be met. The "early" or limited invasive carcinoma requires maximal diagnostic efforts. It is no coincidence that the introduction and acceptance of fiberoptic endoscopy in this country followed the development and widespread use of these instruments in Japan. The declining incidence of this neoplasm in this country does not eliminate its importance. Since we do not understand the reasons for its decreasing incidence, we have no guarantee that this situation will continue.

The symptoms of gastric malignancy while not always typical of peptic disease, are of no help in the differentiation from benign disease. And while the absence of acid after histolog stimulation mandates removal of an ulcer, the presence of acid is little security against the presence of cancer.²

The locations of benign and malignant ulcers is of little value in diagnosis as both occur more commonly on the lesser curvature of the stomach and in the lower one-half of the stomach.²

The reasons for failure of upper-gastrointestinal roentgenography to diagnose cancer when present may be multiple. In some instances the examination may be less than optimal due to poor patient cooperation. In others it may simply reflect the smallness of the lesion which has not yet developed the ominous characteristics of mass, rigidity and altered mucosal folds. These characteristics, by their nature, are associated with late or invasive malignancy.

Rigid criteria must be met to justify a conservative, non-surgical approach to the treatment of

gastric ulcer. Evidence of 50% healing in two to three weeks is mandatory. Endoscopic correlation and a negative biopsy lend a high degree of certainty to a benign roentgenographic impression. The presence of gastric acid is a necessity to allow an interval of healing to occur.

The problem of a normal upper-gastrointestinal roentgenogram with cancer being present, while uncommon, was present in five of our fifty-two patients. Aside from one patient with recurrent cancer in a Billroth II anastomosis, the other four patients were investigated because of pain or bleeding, and all had early carcinoma diagnosed at gastroscopy.

As noted, biopsy was very helpful in many equivocal lesions. Delay in endoscopic diagnosis doubtlessly could have been avoided in three out of four patients had this technique been available. This additional diagnostic refinement added to the new excellent fiberoptic esophagogastrroduodenoscopes has made endoscopic examination of the upper-gastrointestinal tract a crucial diagnostic test. Older² and even current reports⁸ that have suggested an insignificant role for endoscopy do not reflect the use of modern fiberoptic endoscopy that is now available in the practice of gastroenterology.^{9,1}

We feel that a diagnosis of gastric ulcer is an indication for endoscopic evaluation of the stomach. The presence of unexplained pain, weight loss, anemia or frank gastrointestinal hemorrhage

likewise require a consideration of esophagogastrroduodenoscopy. The risk is almost negligible with a trained endoscopist. Patient discomfort is low and the diagnostic yield is rewarding.

Summary

Fifty-two patients with adenocarcinoma of the stomach and six patients with primary malignant lymphoma of the stomach have been examined by fiberoptic esophagogastrroduodenoscopy. The combined accuracy of upper-gastrointestinal roentgenogram and endoscopy at the initial examination or within three months follow-up was 95% in the diagnosis of malignancy. Upper GI series alone suggested a diagnosis of malignancy of the stomach in 63% of the patients. The correct diagnosis was made at endoscopy and biopsy in 54 of the 58 patients on initial examination.

Resectability of the lesions was inversely related to size and was greater in those lesions thought benign on x-ray examination. Radiographic accuracy was directly related to the size of the carcinomas.

These malignant ulcers represent a selected ulcer population as not all gastric ulcers or carcinomas are examined endoscopically.

Acknowledgment

The authors wish to extend their appreciation to Judith Rene Belsito for her help and technical assistance on this paper.

Duodenoscopy and Retrograde Cholangiopancreatography

A New Method for Diagnosis of Obstructive Jaundice

PAUL B. DICKINSON, M.D.,* and ALPHONSO A. BELSITO, M.D.*

DIAGNOSIS OF the cause of jaundice can on many occasions be accomplished by clinical and laboratory data, but, in some individuals accurate diagnosis demands demonstration of the patency or lack of patency of the bile ducts. In patients who have obstructive jaundice, preoperative demonstration of the anatomic site and cause of obstruction provides very useful information at the time of surgery. Until recently, opacification of the bile ducts in the jaundiced patient for roentgenographic recording could only be accomplished by injection of contrast medium into the bile ducts by the percutaneous transhepatic method or the transjugular technique.^{1,2} The availability of sophisticated fiber duodenoscopes has made possible another method of obtaining high quality cholangiograms. With these instruments, the duodenal papilla can be located and under direct vision a cannula placed in the Ampulla of Vater through which contrast medium is injected in a retrograde fashion to opacify the biliary and/or pancreatic ductal systems.³⁻⁷

The following report assesses the value of this new procedure, duodenoscopy with retrograde cholangiopancreatography, in the investigation of individuals suspected of having obstructive jaundice.

Material and Methods

The patients in this series were seen in the private practice of consultative internal medicine and gastroenterology. The clinical and biochemical data of jaundiced patients was reviewed and if hepatitis could be reasonably excluded these patients were considered candidates for the retro-

grade endoscopic approach. An attempt was made to obtain diagnostic information by intravenous cholangiography if the serum bilirubin was 6 mg% or less. If intravenous cholangiography was not possible or non-diagnostic and the patient was an acceptable candidate for exploratory laparotomy, duodenoscopy and retrograde cholangiography were attempted.

The instrument used was the JF-B fiberoptic duodenoscope manufactured by the Olympus Corporation. The CLE Olympus light source was used for all of the examinations. The instrument has a working length of 1200 mm., is 10 mm. in diameter, and has an internal channel through which a cannula can be passed into the field of vision. The examinations were performed in five different community hospitals and since the equipment is portable, the same instrument was used for all of the examinations.

The procedure is performed in a radiology examining room that is equipped with fluoroscopy and a television monitor. Video-tape synchronization with instantaneous replay capability is ideal because it decreases radiation exposure to the patient, personnel, and the instrument. Patient preparation is the same as for upper GI endoscopy. Glucagon and atropine are administered intravenously as needed during the procedure to paralyze the duodenum. The techniques used to locate and intubate the duodenal papilla have been described by Vennes and Silvis.⁷

The contrast medium used is methylglucamine diatrizoate-60. The contrast medium is injected with gentle manual pressure and the injection is continually monitored by fluoroscopy. If the gallbladder is intact, up to 40 cc of contrast medium can be safely placed in the biliary tract. The roentgenographic techniques used have been previously reported.⁸

Results

Duodenoscopy with retrograde cholangiopancreatography was attempted in 266 patients. Jaundice of uncertain etiology was the primary indication for the procedure in 56 of these 266 patients. Results of attempted cholangiopancreatography in these jaundiced patients are graphically illustrated in Figure 1. Papillary intubation was not accomplished in two. In one patient the papilla could not be identified and in another patient a mass deformity of the duodenal loop from carcinoma of the head of the pancreas caused such distortion of the duodenal anatomy that cannulation was not attempted. The papilla was cannulated in 54 patients. These 54 were classified in four ways according to the ductal system, if any, which was opacified. Figure 1 presents the results in that fashion: Group I-Cholangiogram only—five, three of these five cholangiograms were abnormal. Group II-Cholangiopancreatogram—26; 24 of these 26 studies were abnormal for the reasons listed in Figure 2. Group III-Pancreatogram only—19; five of these 19 pancreatograms demon-

strated a dilated and poorly draining duct. These five patients had carcinoma of the head of the pancreas. Group IV-No retrograde flow in either ductal system—four; all of these patients had ampullary obstruction. Figures 2, 3 and 4 are representative of abnormal cholangiograms.

An adequate cholangiogram in summary was obtained in 31 of the 56 jaundiced patients, and in six patients, the pancreatogram alone was diagnostic for the cause of jaundice. An endoscopic diagnosis of carcinoma of the head of the pancreas was made in two patients in which cholangiography was not successful. Therefore, duodenoscopy with retrograde cholangiopancreatography was of diagnostic value in 39 of the 56 patients (72%).

There were 23 patients (Groups III and IV) in which the papilla could be intubated but contrast material could not be injected into the biliary tract. Ten of these 23 had surgically proven ampullary obstruction from neoplasm, calculus, or stricture. The remaining 13 were judged to be technical failures because intravenous cholangiography performed during remission of jaundice, or operative

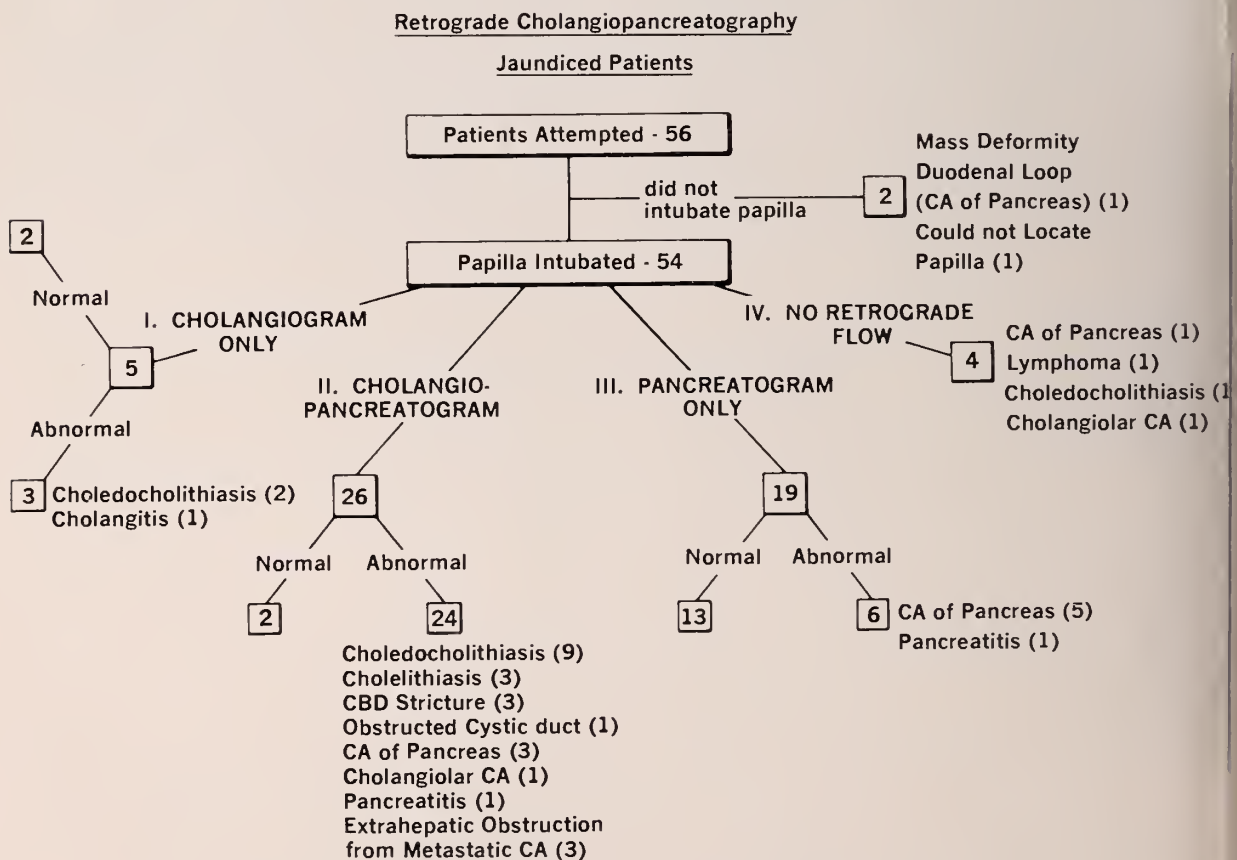

Fig. 1—Results of duodenoscopy with retrograde cholangiopancreatography in patients suspected of having obstructive jaundice.

Fig. 2—Retrograde cholangiogram of a 76 y.o. female who had sudden onset of right upper quadrant pain 36 hours prior to procedure. Arrow points to 12 mm. calculus in the mid common bile duct. Pancreatic duct partially dilated. Radiolucent defects in pancreatic duct represent air bubbles.

Fig. 3—Retrograde cholangiopancreatogram obtained in a 72 y.o. female who presented with painless jaundice. Biliary and pancreatic ducts are obstructed from carcinoma of the head of the pancreas. The lesion was unsectable.

cholangiography, disclosed normal biliary ducts. It is significant that 10 of these 13 technical failures occurred in our first 100 attempts with the procedure.

Complications

Elevations of serum or urine amylase occurred in 80% of the patients studied. The greatest elevations occurred in the individuals that had pancreatography. These amylase elevations were transient, returning to normal by 18 hours after the procedure. Patients occasionally experienced brief mid-abdominal and/or back pain with injection of contrast medium. The severity and duration of pain was poorly correlated with the amylase rise. Cholangitis with sepsis was the most serious complication. This complication occurred in three patients. These individuals all had common bile duct obstruction. We have not encountered this complication since initiating a program of prophylactic antibiotics and immediate surgical decompression of the obstructed duct.

Discussion

Duodenoscopy with retrograde cholangiopancreatography was attempted in 56 patients with suspected obstructive jaundice. The anatomic site of biliary tract obstruction was located in 33 patients and the biliary tract was demonstrated to be patent in four others. The alternative to

Fig. 4—Post-hepatic obstruction by metastatic synovial sarcoma. Z—irregularly compressed common bile duct; X—Dilated cystic duct, (previous cholecystectomy); O—dilated common hepatic duct.

performing endoscopic cholangiopancreatography in these patients would have been a period of observation followed by transhepatic or operative cholangiography if indicated. The diagnosis could have been established by these conventional diagnostic approaches but not without exposing the patient to greater risk. The operative mortality in obstructive jaundice is directly related to the duration and severity of the jaundice.⁹ Exploratory laparotomy can be hazardous if the patient has hepatitis.¹⁰ Therefore, a period of observation is prudent unless obstructive jaundice can be established soon after onset of jaundice. The transhepatic method can demonstrate the site of obstruction and in one series has provided a high success rate.¹¹ This is not a uniform experience and the transhepatic method is generally used as a preoperative procedure.^{1,12} The retrograde method avoids the risk accompanying the transhepatic method and commitment of the patient to surgery. The working approach towards suspected obstructive jaundice should include an attempt at the retrograde method first. If the retrograde method is not successful an attempt at transhepatic cholangiography should then be considered before surgical exploration.

Blumgart et al. were able to establish a definitive diagnosis in 75% of 87 jaundiced patients

by endoscopic cholangiopancreatography.¹³ A similar success rate in jaundiced patients has been reported by Cotton et al. (77% of 30 patients) and Vennes and Silvis (78% of 26 patients).^{7,14} It is to be emphasized that this report and other publications concerning the value of this new procedure include early attempts during which the technique was developed.^{15,16,17} Our success rate in obtaining diagnostic information has improved with experience and modifications in technique and cannula design.

The value of endoscopic cholangiopancreatography in the jaundiced patient is its unique ability to establish, at low risk, without precommitment to surgery, the anatomy of the bile and pancreatic ducts early in the course of jaundice. With this information a firm diagnosis of the cause of jaundice can be established, unnecessary surgery avoided, and appropriate surgery commenced without delay.

Acknowledgments

We gratefully acknowledge the patience and expert assistance of Mrs. Catherine Dian, R.N. We wish also to acknowledge the cooperation and support extended to the authors by the radiology departments of Bethesda Lutheran Hospital, United Hospitals, Inc., Miller Division, Midway Hospital, and St. John's Hospital in St. Paul, Minnesota, and Divine Redeemer Memorial Hospital in South St. Paul, Minnesota, where the retrograde cholangiopancreatograms were performed.

A DOUBLE-DUTY DIURETIC

DYAZIDE[®]

Each capsule contains 50 mg. of Dyrenium[®] (brand of triamterene)
and 25 mg. of hydrochlorothiazide.

GETS THE WATER OUT IN EDEMA

BRINGS DOWN BLOOD PRESSURE IN HYPERTENSION*

SPARES POTASSIUM IN BOTH

Before prescribing, see complete prescribing information in K&F literature or PDR.

Indications: Edema associated with congestive heart failure, cirrhosis of the liver, the nephrotic syndrome; steroid-induced and idiopathic edema; edema resistant to other diuretic therapy. Also, mild to moderate hypertension.

Contraindications: Pre-existing elevated serum potassium, hypersensitivity to either component. Continued use in progressive renal or hepatic dysfunction or developing hyperkalemia.

Warnings: Do not use dietary potassium supplements or potassium salts unless hypokalemia develops or dietary potassium intake is markedly impaired. Enteric-coated potassium salts may cause small bowel stenosis with or without ulceration. Hyperkalemia (> 5.4 mEq/L) has been reported in 4% of patients under 60 years, in 12% of patients over 60 years, and in less than 8% of patients overall. Rarely, cases have been associated with cardiac irregularities. Accordingly, check serum potassium during therapy, particularly in patients with suspected or confirmed renal insufficiency (e.g., elderly or diabetics). If hyperkalemia develops, substitute a thiazide alone. If spironolactone is used concomitantly with Dyazide, check serum potassium frequently — both can cause potassium retention and sometimes hyperkalemia. Two deaths have been reported in patients on such combined therapy (in one, recommended dosage was exceeded; in the other, serum electrolytes were not properly monitored). Observe patients on Dyazide regularly for possible blood dyscrasias, liver damage or other idiosyncratic reactions. Blood dyscrasias have been reported in patients receiving Dyrenium (triamterene, SK&F). Rarely, leukopenia, thrombocytopenia, agranulocytosis, and aplastic anemia have been reported with the thiazides. Watch for signs of impending coma in acutely ill cirrhotics. Thiazides

are reported to cross the placental barrier and appear in breast milk. This may result in fetal or neonatal hyperbilirubinemia, thrombocytopenia, altered carbohydrate metabolism and possibly other adverse reactions that have occurred in the adult. When used during pregnancy or in women who might bear children, weigh potential benefits against possible hazards to fetus.

Precautions: Do periodic serum electrolyte and BUN determinations. Do periodic hematologic studies in cirrhotics with splenomegaly. Antihypertensive effects may be enhanced in postsympathectomy patients. The following may occur: hyperuricemia and gout, reversible nitrogen retention, decreasing alkali reserve with possible metabolic acidosis, hyperglycemia and glycosuria (diabetic insulin requirements may be altered), digitalis intoxication (in hypokalemia). Use cautiously in surgical patients. Concomitant use with antihypertensive agents may result in an additive hypotensive effect.

Adverse Reactions: Muscle cramps, weakness, dizziness, headache, dry mouth; anaphylaxis; rash, urticaria, photosensitivity, purpura, other dermatological conditions; nausea and vomiting (may indicate electrolyte imbalance), diarrhea, constipation, other gastrointestinal disturbances. Rarely, necrotizing vasculitis, paresthesias, icterus, pancreatitis, and xanthopsia have occurred with thiazides alone.

Supplied: Bottles of 100 capsules.

Where "The Pill" Began

Note: Oral contraceptives are complex medications. As with all medications they should be prescribed with discriminating care, and only after reference to full prescribing information. For brief summary of prescribing information, please see next page.

ly on animal studies.

If one "pill" were right for every woman, we'd make it.

Ovulen® Available in 20-, 21- and 28-pill schedules

Each white tablet contains: ethynodiol diacetate 1 mg./mestranol 0.1 mg.
Each pink tablet in Ovulen-28® is a placebo, containing no active ingredients.

Demulen® Available in 21- and 28-pill schedules

Each white tablet contains: ethynodiol diacetate 1 mg./ethinyl estradiol 50 mcg.

Each pink tablet in Demulen-28® is a placebo, containing no active ingredients.

Actions—Ovulen and Demulen act to prevent ovulation by inhibiting the output of gonadotropins from the pituitary gland. Ovulen and Demulen depress the output of both the follicle-stimulating hormone (FSH) and the luteinizing hormone (LH).

Special note—Oral contraceptives have been marketed in the United States since 1960. Reported pregnancy rates vary from product to product. The effectiveness of the sequential products appears to be somewhat lower than that of the combination products. Both types provide almost completely effective contraception.

An increased risk of thromboembolic disease associated with the use of hormonal contraceptives has now been shown in studies conducted in both Great Britain and the United States. Other risks, such as those of elevated blood pressure, liver disease and reduced tolerance to carbohydrates, have not been quantitated with precision.

Long-term administration of both natural and synthetic estrogens in subprimate animal species in multiples of the human dose increases the frequency of some animal carcinomas. These data cannot be transposed directly to man. The possible carcinogenicity due to the estrogens can be neither affirmed nor refuted at this time. Close clinical surveillance of all women taking oral contraceptives must be continued.

Indication—Ovulen and Demulen are indicated for oral contraception.

Contraindications—Patients with thrombophlebitis, thromboembolic disorders, cerebral apoplexy or a past history of these conditions, markedly impaired liver function, known or suspected carcinoma of the breast, known or suspected estrogen-dependent neoplasia and undiagnosed abnormal genital bleeding.

Warnings—The physician should be alert to the earliest manifestations of thrombotic disorders (thrombophlebitis, cerebrovascular disorders, pulmonary embolism and retinal thrombosis). Should any of these occur or be suspected the drug should be discontinued immediately.

Retrospective studies of morbidity and mortality conducted in Great Britain and studies of morbidity in the United States have shown a statistically significant association between thrombophlebitis, pulmonary embolism, and cerebral thrombosis and embolism and the use of oral contraceptives. There have been three principal studies in Britain¹⁻³ leading to this conclusion, and one⁴ in the United States. The estimate of the relative risk of thromboembolism in the study by Vessey and Doll³ was about sevenfold, while Sartwell and associates⁴ in the United States found a relative risk of 4.4, meaning that the users are several times as likely to undergo thromboembolic disease without evident cause as non-users. The American study also indicated that the risk did not persist after discontinuation of administration and that it was not enhanced by long-continued administration. The American study was not designed to evaluate a difference between products. However, the study suggested that there might be an increased risk of thromboembolic disease in users of sequential products. This risk cannot be quantitated, and further studies to confirm this finding are desirable.

Discontinue medication pending examination if there is sudden partial or complete loss of vision, or if there is a sudden onset of proptosis, diplopia or migraine. If examination reveals papilledema or retinal vascular lesions medication should be withdrawn.

Since the safety of Ovulen and Demulen in pregnancy has not been demonstrated, it is recommended that for any patient who has missed two consecutive periods pregnancy should be ruled out before continuing the contraceptive regimen. If the patient has not adhered to the prescribed schedule the possibility of pregnancy should be considered at the time of the first missed period.

A small fraction of the hormonal agents in oral contraceptives has been identified in the milk of mothers receiving these drugs. The long-range effect to the nursing infant cannot be determined at this time.

Precautions—The pretreatment and periodic physical examinations should include special reference to the breasts and pelvic organs, including a Papanicolaou smear since estrogens have been known to produce tumors, some of them malignant, in five species of subprimate animals. Endocrine and possibly liver function tests may be affected by treatment with Ovulen or Demulen. Therefore, if such tests are abnormal in a patient taking Ovulen or Demulen, it is recommended that they be repeated after the drug has been withdrawn for two months. Under the influence of progestogen-estrogen preparations preexisting uterine fibromyomas may increase in size. Because these agents may cause some degree of

fluid retention, conditions which might be influenced by this, such as epilepsy, migraine, asthma, cardiac or renal dysfunction, require careful observation. In breakthrough bleeding, and in cases of irregular bleeding per vaginam, nonfunctional causes should be borne in mind. In undiagnosed bleeding per vaginam adequate diagnostic measures are indicated. Patients with a history of psychic depression should be carefully observed after the drug discontinued if the depression recurs to a serious degree. The possible influence of prolonged Ovulen or Demulen therapy on the pituitary, ovarian, adrenal, hepatic or uterine function awaits further study. A decrease in glucose tolerance has been observed in a significant percentage of patients on oral contraceptives. The mechanism of this decrease is obscure. For this reason, diabetic patients should be carefully observed while receiving Ovulen or Demulen therapy. The age of the patient constitutes no absolute limitation for, although treatment with Ovulen or Demulen may mask the onset of the climacteric. The pathologist should be advised of Ovulen or Demulen therapy when relevant specimens are submitted. Susceptible women may experience an increase in blood coagulation following administration of contraceptive steroids.

Adverse reactions observed in patients receiving oral contraceptives—A statistically significant association has been demonstrated between use of oral contraceptives and the following serious adverse reactions: thrombophlebitis, pulmonary embolism and cerebral thrombosis.

Although available evidence is suggestive of an association, a relationship has been neither confirmed nor refuted for the following serious adverse reactions: neuro-ocular lesions, e.g., retinal thrombosis and optic neuritis.

The following adverse reactions are known to occur in patients receiving oral contraceptives: nausea, vomiting, gastrointestinal symptoms (such as abdominal cramps and bloating), breakthrough bleeding, spotting, change in menstrual flow, amenorrhea before and after treatment, edema, chloasma or melasma, breast changes (tenderness, enlargement and secretion), change in weight (increase or decrease), changes in cervical erosion and cervical conditions, suppression of lactation when given immediately postpartum, cholestatic jaundice, migraine, rash (allergic), rise in blood pressure in susceptible individuals and mental depression.

Although the following adverse reactions have been reported in users of oral contraceptives, an association has been neither confirmed nor refuted: anovulation post treatment, premenstrual syndrome, changes in libido, changes in appetite, cystitis-like syndrome, headache, nervousness, dizziness, fatigue, backache, hirsutism, loss of scalp hair, erythema multiforme, erythema nodosum, hemorrhagic eruption and itching.

The following laboratory results may be altered by the use of oral contraceptives: hepatic function: increased sulfobromophthalate retention and other tests; coagulation tests: increase in prothrombin, Factors VII, VIII, IX and X; thyroid function: increase in PBI, butanol extractable protein bound iodine, and decrease in uptake values; metyrapone test and pregnanediol determination.

SEARLE Products of Searle & Co.
San Juan, Puerto Rico 00936

Enovid-E® Now available in the 21-pill schedule in refillable Compact® and three-cycle Triopak™

Each tablet contains: norethynodrel 2.5 mg./mestranol 0.1 mg.

Actions—Enovid-E acts to prevent ovulation by inhibiting the output of gonadotropins from the pituitary gland. Enovid-E depresses the output of both the follicle-stimulating hormone (FSH) and the luteinizing hormone (LH).

Indication—Enovid-E is indicated for oral contraception. The Special Note, Contraindications, Warnings, Precautions and Adverse Reactions listed above for Ovulen and Demulen are applicable to Enovid-E and should be observed when prescribing Enovid-E.

Enovid-E®

brand of norethynodrel with mestranol

SEARLE Product of Searle Laboratories

Fiberoptic Endoscopy

THIS ISSUE OF MINNESOTA MEDICINE is devoted to fiberoptic endoscopy which has found a place in several specialties of medicine and surgery, substantially within the past decade. Undoubtedly, diagnosis and treatment have been most affected in the field of Gastroenterology as reflected by the papers appearing in preceding pages.

Morrissey's¹ review of gastroscopy in 1967 provides a brief chronicle of the early application of fiberoptics to the gastrointestinal tract. At that time, instruments which allowed reasonably accurate and complete visualization of the stomach had just come into use. The duodenum was only inconsistently visualized. Instruments with biopsy capability were being introduced but had not found widespread use.

In the few years since then, we have seen the development and distribution of a new generation of gastrointestinal fiberoptic endoscopes which allow for safe, comfortable and accurate inspection of the esophagus, stomach, duodenum and colon. Directed biopsies can be taken without undue risk providing for accurate differentiation of benign from malignant lesions, as well as determination of the specific type of malignancy.[†] When used carefully and consistently, gastroscopy with biopsy should allow a rational therapeutic approach to gastric ulcers without the lurking un-

certainty as to whether a lesion is occultly malignant. Diagnosis of malignant lesions should be obtainable immediately, without the traditional follow-up Xrays to demonstrate lack of healing, and earlier surgery may then be possible.

Cannulation of the pancreatic and common bile ducts can now be accomplished relatively easily, and contrast Xrays obtained of these duct systems thus aiding in the differential diagnosis of jaundice and adding another means of investigating the elusive pancreas. These techniques are dealt with in the contributions by Dr. Vennes[‡] and Drs. Dickinson and Belsito.[#]

Perhaps the most interesting development in gastrointestinal endoscopy is the therapeutic application of these instruments with removal of polypoid lesions from the colon as discussed by Chally and Blackwood[§] and gastric polypectomy.[¶] It will be of great importance to determine the impact of early polyp removal on the occurrence of carcinoma in the stomach and colon, but at least, resective biopsy is an important step forward in accurate diagnosis.

Similarly, gains have been made in the examination of the tracheobronchial tree as reported by Stubbs and Rosenow^{||} and the utilization of laparoscopy[°] (Johnson and Smith).

These new tools have already had significant impact in the clinical practice of medicine, and it is exciting to contemplate the improved instrumentation likely to develop within the next few years with resulting improvements in patient care.

NRMP Reports

WITH THIS ISSUE subscribers to MINNESOTA MEDICINE receive a supplement containing 21 reports covering 29 Research and Development activities supported by Northlands Regional Medical Program (NRMP) during the past year. I am proud to have been given the opportunity to serve as "Guest Editor" of a supplement for the second time within 12 months. Derivation of the theme behind contents of the two issues reveals a fundamental change from emphasis on continuing education of health professionals to multiple problems relating more specifically to improved delivery of health care services. Problem areas include quality of care, more relevant health manpower and improved accessibility. The "state of the art" is analyzed; plans are presented for improvements; and demonstrations are reported with evaluation of results.

The 46 authors in the present series did a commendable job in presenting results of their studies in a concise and understandable manner. The enthusiasm of these and other NRMP project personnel has been stimulating and infectious. Four additional articles originally planned for this series could not be completed in time for publication. Areas covered include: evaluation of care in the Intensive Care Units of 67 Minnesota Hos-

pitals, demonstration of primary prevention rheumatic fever and two additional studies ambulatory care. These interesting project activities will be reported later in this or other journals.

It was an additional pleasure for me to arrange for the nine editorials in this issue which help interpret the significance of the reports presented.

As NRMP is phased out or radically changed, special recognition is appropriate for members of the program staff—both past and present. Several are authors of articles in this series, and two others were authors in the December 1972 supplement. About 25 other members of the professional staff have contributed significantly to these and other NRMP activities during the past six years even though they have not received recognition as authors in "Minnesota Medicine." Most staff members who have left or will soon leave NRMP have secured employment in other health-related institutions in Minnesota. The people participating in NRMP—staff, project personnel, Board, Regional Advisory Group, and Committees—constitute the most important legacy of this program for constructive improvements in health care in Minnesota.

Winston R. Miller, M.D.
Guest Editor

Northlands Regional Medical Program (NRMP)*

MINNESOTA MEDICINE with this issue publishes the second supplement provided by the NRMP (The first was the supplement to the December 1972 issue).

NRMP has examined the cost and distribution of health care in Minnesota, and this report is undoubtedly the most complete on the present local condition. We are a hard-working profession as Hill, Miller, and Campbell† point out and their survey indicates we work about 55 hours a week, see 100 patients in the office per week (if we do not practice in the Mayo Clinic) and spend 35% of our time in the hospital. We are well paid, earning the national average about 39.5 thousand dollars annually. Obstetricians earn the most, 15% above the average, and pediatricians are low

on the totem pole, less 8.5%. We are just beginning to employ nurse practitioners and other types of physician's assistants. Several papers in this supplement deal with these assistant types. There are a number of interesting programs in the state established or under consideration devoted to the training of such assistants: St. Cloud, the University of Minnesota and the Mayo Clinic. With the continued unmet need for medical services there is no doubt these assistants will be called upon more and more in the years immediately ahead.

A medical group in Virginia is making use of a computer to analyze their own practice as reported by Friedlieb.‡ They improve the quality of their work by reporting to their colleagues the

*Supplements to MINNESOTA MEDICINE are published at no expense to the Minnesota State Medical Association or MINNESOTA MEDICINE.

†See page 58 of the Supplement.

‡See page 44 of the Supplement.

performance versus criteria. Thus they now know that with the diagnosis of acute bronchitis their records show mention of sputum production in only 26% of their cases. With this information available to their clinic physicians it is likely the next survey will show greater attention to this detail.

In Virginia it costs a patient \$40-\$50 per year for physician care if he has diabetes or ischemic heart disease (chronic illness). Acute diseases such as cystitis or otitis media cost \$14-\$25. (I hesitate to parade these figures for fear our Twin

Cities patients will flock to the Range for their care. These are modest charges indeed.)

NRMP in its seven years of existence has made an important contribution to medicine in Minnesota and the upper midwest. The region and the nation have benefited by its work in coronary care units, in assessing medical needs in the area, in indicating how urgent medical problems are likely to be solved. We owe a debt to NRMP and to its only director throughout its existence, Winston Miller.

Flexible Fiberoptic Bronchoscopy

STUBBS AND ROSENOW* have in their paper on flexible fiberoptic bronchoscopy given us a beautiful account of this new procedure. They with their large experience point out the many details which have to be considered to realize its full potential. Their paper should be read carefully by those interested in taking advantage of this technique. Flexible bronchoscopy does not replace the classical procedure but complements it in equal proportion. Rigid bronchoscopy has to be used with bleeding or in the treatment of foreign bodies because of the small channel in the flexible instrument. A great advantage of the latter is that it can be inserted into the segmental bronchi which can be examined and brushed directly. Further, it is much easier on the patient. There is a controversy as to whether the instrument should be passed through the nares or with an endotracheal tube. The use of the latter, as they indicate, is probably better because it allows the instrument or brush to be removed repeatedly for cleaning or sampling. Stubbs and Roscnaw

emphasize that since the newer procedure is not so disagreeable as the old, haste can be avoided and follow up studies undertaken. They repeat that good anesthesia requires time and careful preparation. Logistic implications of this new development can be anticipated. The authors conduct flexible bronchoscopy adjacent to the operating room area. I believe this is very important because the instrument is being touted as something which can be used by anyone on the wards or in the office. The combination of a patient with lung disease, local anesthesia, and the introduction of tubes through the airway may produce cardiac arrhythmia or even arrest. Patients should have their electrocardiogram monitored during the procedure and adequate personnel ought to be available if complications arise. Finally, this instrument is delicate and must be handled gently both in its cleaning and use. Its introduction is one of the important advances in our armamentarium over the past decade.

*See page 831.

Luverne W. Johnsrud, M.D.

A memorial fund in the honor of the late Dr. Luverne W. Johnsrud has been established with the Minnesota Medical Foundation at the University of Minnesota. The purpose of the fund which exceeds \$10,000 is to assist needy medical students with long term low cost loans to finance their medical education at the University of Minnesota or UMD. Iron Range Area students will be given priority consideration in the disbursement of the loan funds.

Gastric Malignancy

Gastroscopic Experience

ENDOSCOPY OF the upper gut has enjoyed a renaissance in the past five to 10 years, following the introduction of flexible fiberoptic instruments. These allow a safe, relatively comfortable examination. Areas previously inaccessible can be visualized and biopsy capabilities give additional advantage. But the true role of endoscopy in specific patients and in specific conditions has not yet been well defined. Anecdotal reports and ill-defined patient selection might lead the casual reader to overestimate its value.

Belsito and Dickinson* help us to some extent. They review 58 cases of proven malignancy occurring in 600 patients with ulcerating gastric lesions. These 58 were divided into five groups on the basis of endoscopic and roentgenographic diagnosis (or lack of diagnosis) of the malignancy.

Results in their 15 patients (26% of the total) in group II clearly establish endoscopy as being useful in selected patients. Whereas the roentgenograms of all of these patients had been reported as "negative" or "benign gastric ulcer," endoscopy in all of them provided a correct diagnosis of malignancy. But it is quite disturbing that apparently in only one of the 15 patients was biopsy positive, the rest apparently having either no biopsy or a negative biopsy. Another disturbing point is that, with respect to these other 14 patients, the authors were able by gross evaluation of the lesion to say only "suspicious for malignancy" or "can't rule out malignancy." Let the experience of these highly qualified endoscopists be a caution to the inexperienced "hobbyist" who dabbles in endoscopy (for the fun of it—or for more ulterior purposes). And, probably more importantly, let it be a caution to those who would refer patients to him.

This article, while reaffirming that endoscopy *can* be of value, still leaves us seeking an answer to the larger question of when (and sometimes whether) one should use it in evaluating a specific gastric lesion. For example, in four of the five patients in group III ("delayed diagnosis") a positive endoscopic diagnosis was indeed made when they were first examined. But in all four the ulcer had not healed over three to 12 months,

which in itself is an indication for operation. What if any extenuating circumstances existed to prompt the endoscopy? And with respect to group I (both roentgenographically and endoscopically positive) one must also ask how many patients *needed* the endoscopy. How many had a large mass, or other roentgenographic signs (or evidence from history, physical examination, and laboratory testing), that indicated a need for operation? How many would have undergone operation even if the endoscopist had reported a benign lesion? Some patients may have had associated conditions that made operation undesirable until more conclusive proof of malignancy was obtained, but how many?

Two patients (one in group III and one in group IV) had cancer that was not correctly diagnosed by endoscopy, either grossly or with biopsy. This observation should be viewed not as a condemnation of the procedure but rather as a realistic commentary that no procedure, even the best, is infallible.

Criticism of endoscopy has arisen from within and without the medical profession. Claims of overuse, overcharge, lack of value, and inaccuracy of diagnosis have certain justification. Minnesota is fortunate in having several groups who have had long-standing experience in endoscopy. Such groups have an opportunity to define the proper place for their procedure. And the first question, as they hammer out this definition, should be, "Do the results of the examination in any real way alter the patient's diagnosis or management? Unless and until the answer to this question is sought and defined for a specific patient or a specific condition, endoscopy must tend to remain at the level of the automated blood tests; for example, everyone gets a bilirubin determination whether he needs it or not. The collaborative efforts of an endoscopist, a surgeon, a radiologist, and a gastroenterologist not practicing endoscopy would give balance to an investigative team. A retrospective study would be very helpful; a prospective study, while harder to do, would be even better.

Philip W. Brown, Jr., M.D.
Rochester, Minnesota

Gynecologic Laparoscopy

LAPAROSCOPY BOTH diagnostic and for the performance of procedures such as tubal sterilization has become firmly established in the past one to two years. Where the procedure was hardly known a short time ago, it is quite common on the surgical schedule of any large hospital.

The equipment in use today has been improved and simplified so that its use is relatively simple. Nevertheless, the procedure is not without potential problems. Abdominal wall hematomas, bowel perforations by trocar or cautery tip, bladder injuries, bleeding from biopsy sites of tubal sterilization are well known.

The authors of Gynecologic Laparoscopy* mention that acid base balance from CO₂ absorp-

tion is not a problem due to the short time the pneumoperitoneum is present. However, in the course of training in the techniques of laparoscopy a longer operative time can lead to problems.

Johnson and Smith also mention that catheterization is not necessary. Anyone that has done a laparoscopy on a patient with a full bladder knows the difficulty he has in visualizing the pelvic organs and cauterizing the tubes if sterilization is to be carried out.

The laparoscope will be used more and more often in the future. Good surgical technique should be used and the procedure respected as something more than a quick minor operation.

E. William Haywa, M.D.
Minneapolis, Minnesota

The Minnesota Cervical Cancer Mortality Study

IN THIS ISSUE, there is a preliminary report* from the Committee of Obstetrics, Gynecology and Maternal Health of the Minnesota State Medical Association. It deals with their study of about one-third of those patients who died from cervical cancer during 1971-72. A large part of the report deals with the principles which have been applied and indirectly with the committee's hopes. This is designed to acquaint Minnesota physicians with the general character of the study. It has not progressed sufficiently to justify more than a sketchy report with little in the way of firm conclusions.

The hopes of the committee are based on what is now a recognized conclusion that, in theory at least, the frequently occurring cervical carcinoma can be identified by simple and widely applicable means in its earliest stage when it is for practical purposes completely curable. Failure to achieve such efficiency is the result of faults which are correctable and which involve, among others, both patients and physicians. The committee hopes to define these as they affect local conditions so that they may be corrected.

In reading this report one must bear in mind

the danger of errors inherent in drawing generalized conclusions from material samples limited by definition. The same risk has been recognized by the Minnesota Maternal Mortality Study of obstetric material. These are both studies of deaths, many of which, in some and sometimes considerable degree, are preventable. They are likely then to abnormally concentrate unhappy circumstances which are not necessarily those to which the whole population is subject. The present report states: "Treatment for recurrent or persistent disease . . . Four of these had radical surgery. Except for one postoperative death, the patients succumbed to recurrent disease . . ." Since only deaths are included in the study, this statement indicates nothing whatever as to the adequacy or effectiveness of surgical treatment of persistent or recurrent disease. In lesser degree, the same principle applies to other conclusions.

It is unwise to draw generalized conclusions from such material. However, as from the Maternal Mortality Study, useful information can be obtained. It is this for which the Cervical Cancer Mortality Study is searching. Unacceptable circumstances in prevention, diagnosis and treatment in Minnesota can be found and measures taken to

*See page 9 of the Supplement.

change these. Even though the frequency with which these occur is unknown, the recognition of a few is useful information. That this approach may be effective in the gynecologic cancer field is prettily demonstrated by the gratifying improvement in cure rates in recent years of patients with adenocarcinoma of the endometrium and those with carcinoma of the vulva. Cervical neoplasms offer much greater possibilities of response to ideal handling. The prospect is so pleasing that all of us will take pleasure in the effort to cooperate.

The limitations of a study of mortalities are evident. The details to be derived from such a very early preliminary study are inevitably sketchy. The hope is that a mechanism can be devised which will allow studies of the factors involved in those who survived. So many questions come to mind. What, in Minnesota, is the degree of

efficiency of smear taking and, in particular, of smear-reading? What interpretation is the physician placing on someone else's reports of smears, whether positive, atypical or negative? What further procedures are being carried out for these? What is the overall efficiency of the histologic interpretation of tissue obtained by various means? What is the reality of the reaction to a reported diagnosis of so-called carcinoma in situ? What effect has present understanding of the use of the various tools for diagnosis and treatment had on the total pattern of carcinoma of the cervix in Minnesota? What can be expected from educational pushes in one or other direction? And so on, almost ad infinitum. It is urged that this committee address itself to methods of obtaining such information. The rewards promise to be great.

John L. McKelvey, M.D.
St. Paul, Minnesota

Health Care Delivery

THIS ISSUE OF MINNESOTA MEDICINE is destined to be one of the most referred to issues in the coming years as we see that it begins to address itself to the responsibilities that are being clearly left at the health care industry's door.

Recent legislation has made it clear to all of us that all participants in the delivery of health care in general, and physicians in particular, are to be held accountable for the effective quality assurance program. It has further been recognized that quality assurance has two components, and these components are quality assessment and quality control.

Each of these dimensions is being directed toward three issues: (1) necessity of service rendered, (2) appropriateness of the service (quality and facility), and (3) surveillance of expensive and unusual services.

The aforementioned mandate has become part of the Federal regulatory effort with respect to Medicare and Medicaid patients. We must ask ourselves whether, as professional people, we don't have a responsibility which sweeps beyond that. This responsibility is that of assuring medical care to the entire population of this state. To this end, Northlands Regional Medical Program has taken a mature approach. We have seen, as witnessed in the articles by Friedlieb,* as well as Kraus and

Hanson,* that the skills incident to evaluating ambulatory medical care can be mounted at reasonable costs and directed toward continuing improvement of the quality of medical care within the ambulatory setting. Fortunately, we have seen these same skills applied by Layer and Erickson* in the nursing home setting. These are areas of responsibility not now covered by legal mandate and perhaps through the extension and application of the lessons learned by these authors, we may have an opportunity to see medicine assume the initiative, to enable itself to function without further extension of a regulatory bureaucracy into these areas.

Central to all of the above articles, as well as the article concerning the monitoring of hospital quality and productivity by Upham and Lillquist* is the recognition of the central role the medical record plays in the health care delivery system. It is of interest that the problem oriented medical record as it is addressed by Asp and Brashear* in one article and by Savett and Good* in another, each in and of itself created an activity which in the process of displaying how care was delivered, initiated a change mechanism whereby care could be even further improved.

These articles, then, make it clear that we have the opportunity to carry out evaluatory efforts of all services afforded all patients entrusted to our

*See pages 44, 49, 36, 24, 12 and 19 of the Supplement.

ands. Furthermore, from these efforts, change mechanisms can be mounted which need not threaten or punish.

I am convinced that this unusual granting activity through providing multiple seed grants within the state of Minnesota will be looked on years to come as having been one of the most effective programs our government has ever

undertaken. Now that we have identified the capacity for ongoing review in numerous areas, there is no reason why we should not hold ourselves to the application of these skills wherever patients are served.

Richard E. YaDeau, M.D.
St. Paul, Minnesota

Patient Health Education and the Future

HEALTH CARE IS currently undergoing numerous transitions. Part of that change includes involving the patient or consumer in the overall planning and management of his own disease state. Most of us as physicians have been trained in the traditional principles of the management of acute disease entities or emergency conditions in which we provide an immediate or "active" service to a "passive" patient. The major demands for health care today, however, are no longer conditions that are primarily emergent in nature. The leading causes of death and disability in the United States are now chronic conditions such as heart disease, stroke, diabetes, kidney problems, arthritis, obesity, alcoholism, etc. These entities currently cannot be cured but most of them can be controlled. The most important person in the control of these diseases is the patient himself and members of his family. This means that without the cooperation of an informed, motivated patient, we, as health professionals, are virtually powerless to carry out effective management. To accommodate to these changing needs, effective health care must include not only competent history taking, physical examinations, use of the laboratory and appropriate prescriptions, but also the education and preparation of the patient to carry out an active role in disease management. Undoubtedly most of us, if asked, would reply that we are already providing a great deal of patient education in our offices and in the hospitals we utilize. As we read Mrs. Verstraete's* article "Patient Education In A Health Sciences Center" in this issue of MINNESOTA MEDICINE, most of us would have to re-define our meaning of "education."

National surveys have given us some insight as to just how effective health professionals have been in the education of the general public. In a

National Health Survey, Dr. Glen MacDonald of the U. S. Public Health Service reported that only 10% of diabetics given a dietary prescription demonstrated sufficient knowledge of the subject to carry out the instructions. In a recent Louis Harris Poll, it was found that almost one-third of the respondents could not name even one of the seven warning signs of cancer. When one thinks of the tremendous amount of information distributed in physician's offices, hospitals, and through the American Cancer Society regarding this one area of health, the lack of effective means and modes of patient education is frightening.

Today, consumerism is a popular tidal wave sweeping through many fields and beginning to engulf the health care field. Consumers are demanding to be placed in responsible positions where they have input not only into current health care programs but also in its future planning.

Those of us who already seem overly-busy in practice have grave concerns about the time commitments such educational programs may require. It is important that we understand that this process may not have to be carried out by the physician himself, but other health professionals may be as well or even better qualified to plan, develop, and implement patient education programs. It's encouraging to know that the University of Minnesota will be initiating this concept in their health care curriculum in the fall of 1973. Certainly consumers have been demanding knowledge and input into the management of their disease and the response of the health professions is overdue. Hopefully we can provide knowledge, insight, and increasing capabilities on the part of health professions to fulfill these needs.

The awareness and use of community, state, or regional patient educational resources can also be utilized effectively; for example, the Diabetes Education Center in Minneapolis provides an exten-

*See page 31 of the Supplement.

sive five-day patient education experience where patients and their family members may be referred for an intensive five-day course. Patients then return to their own physicians for ongoing support and care. In our experience at the Center we are repeatedly impressed by the number of patients who ask at the end of the class week, "Why hasn't

this information been taught to me before?" The informed consumer quickly realizes his role in his own care as well as the importance of patient education which permits him to carry out his responsibilities in the management of his own disease.

Donnell D. Etzwiler, M.D.
St. Louis Park Medical Center
and Diabetes Education Center

Effective Rehabilitation Education

REHABILITATION HAS two features which contribute to the complexity of a continuing medical-education program.

It is a comparatively new field, having evolved primarily from the polio epidemics and problems of World War II; therefore, the exposure to rehabilitation in most medical schools' curricula has been limited. As a result many physicians have had to develop an empirical knowledge of the physical modalities and their applications to various diseases and disabilities.

Secondly, to a greater extent than in most other health-care areas, allied health professionals, nurses experienced in long-term care, physical therapists, occupational therapists, etc. are utilized in the rehabilitation field. This diversity and the fact that many persons are involved contributes to the physician's concern about the effective utilization of rehabilitation services, the costs of these services, and the technical competence of the therapists. As a result a continuing medical-education program in rehabilitation must present materials related to patient selection, therapy service utilization, and therapist supervision rather than a singular emphasis on the technical and physical properties of the modalities.

*See page 39 of the Supplement.

The effectiveness of this approach is demonstrated in the article "Improving Rehabilitation Through Continuing Medical Education."* The results support the involved study's hypothesis that a well-planned continuing-education program for the medical staff of a community hospital would: (1) change the characteristics of a physical therapy treatment, and (2) change the patient referral process patterns. In addition the program resulted in a modification of utilization pattern which could be interpreted as the establishment of standards of quality for rehabilitation care in the Northfield City Hospital.

It is of interest that the methodology was developed by professionals who were well acquainted with the needs of the community. Miss Deschler a former practicing physical therapist; Dr. Wood who for many years was a colleague in family practice; and the Northfield City Hospital medical staff were able to identify the topics which would contribute to improved rehabilitation care in the community. This approach in itself assured the success of the educational effort, enabling the authors to relate that the "receptivity by the (medical) staff was enthusiastic."

Loren R. Leslie, M.D.
Minneapolis, Minnesota

Improved Health Care System

WILKINS¹ TRACES the recent development of the Area Health Education Center (AHEC) and the Community-Based Health Education Council (CHEC) mechanisms for facilitating needed improvements in the delivery of health services. Both approaches constitute exploratory efforts to articulate stronger functional relationships among educational institutions, providers and consumers of health services and health professionals in the

community. Both developments grew out of a national trend, spurred by the Carnegie Commission on Higher Education,² the Millis report,³ and consumer concerns, to find a more effective and rational system for the delivery of health care especially in chronically underserved rural and urban locations. Both serve the objectives of providing more and better health manpower by means of coordinative mechanisms which will help estab-

ish genuine and sustainable cooperative bonds between educational programs and the providers and consumers of health care.

The CHEC program is designed to elicit initiative for cooperative effort at the local level while the AHEC utilizes the health sciences center as a focus for developing cooperative programs. As Wilkins points out, the approaches are not mutually exclusive and lend themselves to complementary arrangements for planning, implementation and evaluation of specific programs.

The threat of loss of federal funds for CHEC operations seriously undermines this innovative attempt to improve the effectiveness of health professionals in the community and to increase the responsiveness of the health manpower production system to each planning area of the State. One year is not sufficient to evaluate the community-based model for strengthening cooperative relationships among the varied components of the health care system and for exploring the relationship between the CHEC and AHEC mechanisms. The accomplishments outlined by Wilkins for this first year are most impressive. The expressed commitment of each CHEC to continue operation reflects a unity of purpose which will hopefully be sustained with state and local funds if federal support is withdrawn. The recommendations of a special task force for the State Comprehensive State Planning Agency and the reinforcement provided by the Higher Education Coordinating Commission, as outlined by Wilkins, provide additional support for the need to explore the community-based concept until a reasonable test of its validity can be established.

The account by Draine and Rustad² of the Higher Education Coordinating Commission's effort to generate planning guidelines for nursing education provides an excellent example of HECC's statewide coordinating role in health personnel development. The voluntary mode of coordination encourages open information flow, richly varied group participation and reliance upon data and expertise. It should contribute heavily to the development of a more rational and progressive health manpower production system for the State.

The Advisory Committee on Nursing Education, formed as a part of this effort, performs a crucial role toward synthesizing interests and resolving differences in outlook among the participating educational systems, constituencies of the

multilevel role structure of the nursing profession, nursing students, provider institutions and public representatives of each planning area of the State.

While the project's scope was necessarily limited to supply and demand considerations, the approach should have wide generality in determination of need and specification of quality requirements, not only in nursing education but in other areas of health personnel development as well. Coordination of a myriad of interest groups, for example, is direly needed in allied health education, where a burgeoning proliferation of new programs threatens to add chaos to an already fragmented array of existing programs.

The article by Schnarr and Hessian³ deals with one of the most important and difficult educational issues confronting any multilevel discipline: career mobility from entry to the highest level of competence afforded by a profession. The issue is complicated further by a growing recognition that career goals can change in lateral as well as upward directions. Career goals frequently change with discovery of latent aptitudes and abilities and with attainment of new skills in a functional setting. Acknowledgment of career mobility as a guiding value in educational planning can be understood as an outgrowth of an increased societal commitment to equality of opportunity, whether directed to minority and culturally disadvantaged people or to competent health personnel who are locked into a designated level by an inflexible credentialing system which does not recognize experience-based learning and proficiency.

Schnarr and Hessian delineate the many problems encountered by the experienced nurse in search of a baccalaureate degree and outline the sequence of events which produced a set of challenge examinations. These examinations were designed to objectify individual attainment of concepts and competencies as a basis for determining credit equivalencies toward fulfillment of the requirements of a nursing major.

This was one of several designs to emerge from deliberations of a *Task Force on Career Mobility in Nursing*. Complementary career mobility programs being developed by the University of Minnesota School of Nursing and the Minnesota Nursing Association indicate that the nursing educators of Minnesota are providing timely leadership in this crucial area of educational change.

The underlying rationale and methodologies in-

volved in the programs described in these three articles represent at different levels of application the rapidly expanding commitment of health care educators and professionals to articulate more effective relationships between the community and the health manpower education system. Such efforts should contribute to the development of more skilled health care personnel, better utiliza-

tion and geographic distribution of personnel, improved opportunities in health careers and a more informed and involved consumer of health services—major ingredients of an improved health care system.

Reality Testing Profiles of Medical Practice

IF THE PROFESSION of medicine is unaware of existing medical practices and the public's expectations of those practices, we are indeed lost. Speeches about supposed problems and their solutions will not orient us. Our need is information concerning what is reality.

Minnesota's citizen generally feels he gets good medical care but there are some problems concerning distribution of care, time lags and costs. He feels medicine should show leadership in solving these problems.* The medical profession feels that progress is being made toward increasing the quantity and quality of medical care available to our citizens. Northlands Regional Medical Program involvement in determining these attitudes is significant and now *Profiles of Medical Practice* adds more dimension to the picture by showing what Minnesota's primary and direct patient care physicians are doing along with some insights as to how they are doing it.

The study shows Minnesota physicians now delegate many parts of their work to a significant degree while the public controversy over delegation to and certification of allied health professionals continues.

Using 1969 and 1970 national averages, we find our 54 hour week is 7% longer and we see

9% more patients while spending a few hours less in direct patient care and work one week less per year; also it costs us more in overhead to generate approximately the same net income per year. The patterns of practice among the various specialty sub-groups are shown not to be the same. Hopefully the physician community will evaluate these discrepancies and their implications.

One thousand five hundred and five (44%) of Minnesota's 3,383 primary direct patient care physicians supplied information about their practices. The authors under Northlands Regional Medical Programs auspices analyzed the data and present to us as "*Profiles of Medical Practice*."[†] Whether we discuss medical education, medical care, delivery or distribution, physicians income, delegation of medical care tasks or a host of other problems, this study increases our understanding of where we are now. That is the first step in rational goal determination and the required foundation for implementing action to reach these goals.

Dull statistical reading? Perhaps some will find it so. Inaccurate? Not likely, at least for 44% of Minnesota's physicians. Invalid because of sample bias? Probably not but to be sure you would have to ask the 1,878 non-respondent physicians who failed to help medicine know itself better.

The Physician's Assistant versus the Nurse Associate

[N THIS ISSUE OF MINNESOTA MEDICINE are two articles that present diametrically opposing stands concerning allied health personnel and allied health professionals." It is to the credit of the Northlands Regional Medical Program that these opposing views reflect the NRMP Policy of sponsorship of studies encompassing a broad approach to health care problems.

In their opening paragraph Anderson, Cooley, and Sparrow* discuss changing relationships creating "a need for expanding and redefining the roles . . . the change or metamorphosis of roles . . . of the nurse." "The development of the nurse to her full potential." An historical review follows but nowhere do the authors become specific concerning the opening paragraph.

Although the five objectives cited in the text failed to meet the goals of the opening paragraphs, the authors do develop some interesting material:

1. The courses were taken to the nurse student in rural areas.
2. The courses were designed to serve that long neglected group, the diploma nurses.
3. *The gain in objective medical knowledge by the nurse-trainees was not statistically significant* as demonstrated by pre- and post-course testing.
4. Consumer reaction was good.
5. Defining the dimensions of the nurse practitioner's role in health care delivery has not been accomplished as yet.
6. Continuation of funding was not accomplished.

In the other article Gonzalez* outlines the history of the Physician's Assistant Program and develops two main objectives:

1. Documentation of the need and feasibility for physician assistants.

2. Planning the educational program.

Under the need or feasibility studies, she cited five areas:

- a. Local physician support is definitely positive.
- b. Despite the rejection of physician assistants by organized nursing, nursing support is surprisingly good (90%).
- c. Because of site selection, the scope of this study is skewed toward respiratory, muscle, gyn, and physical examination.
- d. The concise description of the delegatory problem by Gonzalez is the high point of the paper. It is apparent that broad (possibly national) coalition of Pharmacy, Nursing, and Optometry against physician delegation is effective in Minnesota.
- e. Funding is constantly a problem.

The educational planning of curriculum content, length of program and admission policy indicate a moderate departure from existing programs to fit the needs of the college geographical area.

Doctor Gonzalez has presented a course description of a model for the training of a Category I Physician's Assistant in a specific college area.

Of special note is Doctor Gonzalez's recognition of the continuing national pressure of non-medical health "professions" in their apparent self serving attempt to limit delegation by physicians. If 90% of the nurses recognize that delegation by physicians is beneficial to the patient and to the health care system, why is organized nursing so unresponsive to its constituents by condemning delegation to physician assistants? The encouraging note from both of these articles is the broad expanding approach of the Northlands Regional Medical program in the study of health care.

Deprived Medical Care

FOUR ARTICLES in this issue of MINNESOTA MEDICINE are reports of study projects supported by Northlands Regional Medical Program. Each, in some way relates to areas of deprived medical care, and one may note sociological implications.

Two of these studies describe projects designed to define the health status of specific groups of people. One such group was rural, middle class, and white; the other was mixed urban-rural, poor, and Indian. Two of these studies describe projects designed to provide health care in medically deprived communities. One describes the effort to provide medical care within the main stream of American medicine by use of the paramedical aide working in close correlation and under the supervision of an established, multi-specialty clinic. The other describes an attempt to provide health services (as opposed to medical care) by a mobile health unit staffed by nurses and operating abreast of the main stream of American medical care. Although the subject matter in each article seems widely separated from that of the others, there is a common theme, and certain correlations can be drawn.

A study reported here by O'Leary, Zaki and Alexander* indicates that the health status of certain groups may be difficult to define. From this one may deduce that health needs for such a group may be difficult to define, and therefore difficult to provide appropriately.

In contrast, the study reported by McCreary, Deegan and Thompson* describes vividly the health status of their group, and leaves no question that the Indians of Minnesota are deprived medically by any measure of care that one may choose. Associated with this is profound economic

and sociologic deprivation. The authors depict well the interface that exists between health professionals and the Indians, and their suggestion for breaching this barrier is worthy of study by all who provide services to under privileged, minority people.

The study by Snyder and Setter,* as well as that by the Mayo Clinic group* describe interesting projects designed to bring health care into communities where it had not been readily available. The two methods presented are quite in contrast, and one might argue the advantages of one approach as compared to the other. It appears that one or both may gain use in the future. More experimentation is required, and before either of these may gain wide use, certain professional, legal, and ethical standards must be more clearly defined.

Northlands Regional Medical Program has become inoperative due to recent withdrawal of federal funds from support of a wide range of humanitarian activities. The wisdom of this decision at the federal level has been disputed. Also, the need to rely upon the federal government for this support has been questioned. In any case, the old order is changing and with it medical care also. New methods to clarify old problems, and to define new problems must be sought; and new means to resolve these problems must be developed. Northlands Regional Medical Program is to be commended for supporting worthy performance in this area of "sociologic" medicine. Without Northlands Regional Medical Program a void is left. It remains to be seen if this void will be filled, and if so how. One thing is certain, if the void remains, progress in this vital area will be stifled.

Wesley W. Spink Lecture

October 15-19

Dr. Michael Wilson Fox, a veterinarian and associate professor of psychology at Washington University, St. Louis, Missouri, and a pioneering authority on the behavior of dogs and wolves, will deliver the second biennial Wesley W. Spink Lectures on Comparative Medicine during October at Carleton College and the University of Minnesota.

DKQ knows ways designed to keep your investments in good health.

Few people can be competent in two professions. The demanding practice of medicine leaves little time to do another job well.

Managing your investments is a professional job, too. It usually takes more time, specialized education, research, and experience than most people can bring to it.

An investor needs up-to-date knowledge of the economy... knowledge of various industries and of individual companies within those industries... knowledge of listed and unlisted stocks, of mutual funds, and of the bond market... and knowledge of how to maintain an investment portfolio in an up-dated diversified balance that will best match the investor's personal goals.

Such knowledge is what Dain, Kalman & Quail offers. Obtaining, analyzing and utilizing this information is *our* full-time occupation. Behind each broker is our highly capable Research Department,

the largest of any investment firm in the Upper Midwest and one of the largest of any regional investment firm in the nation.

To put it another way, Dain, Kalman & Quail of *time*: time to gather and study in-depth, up-to-date research... time to review your portfolio against your objectives... time to give professional assistance in handling the investments of those who don't have time for this second profession.

If you find you cannot give your portfolio as much knowledgeable attention as it really deserves, we suggest that you contact Bill Hough, Manager of the DKQ office in St. Paul (tel. (612) 371-7650). He will be happy to talk with you. Or fill in the mail the form below and we'll contact you for setting up a convenient appointment. A little of your time could save you a great deal of time. It could also help keep your investments in good health.

An Equal Opportunity Employer.

Letter to the Editor

Cooperation-Competition-Conflict

Concentric Circles of Continuing Comprehensive Care

At the present time the main elements in providing health care are doctors, hospitals, public health departments and third party payors. Think of each of these elements as separate circles and the patient as a fifth circle trying to stay away from all of the delivery circles. As he gets sick, however, the circles move together and we find that there are areas of overlap. The overlap represents areas of potential cooperation, competition and conflict. Cooperation if the patient is hospitalized. Competition in various emergency room and hospital outreach programs. Conflict when insurance policies force patients to use hospital facilities to obtain coverage or when a hospital tries to actually deliver medical care to an area.

Remember a hospital does not, cannot and should not provide medical care but is only one place where that care can be provided.

Delivery of medical care by a hospital usually starts in the guise of medical education with students and residents and a paid staff to teach them and "free" clinics and beds for that teaching. The next step is a hospital based and subsidized clinic to serve an "unmet health need" in an area around the hospital. This area around the hospital then gradually enlarges until each of the hospitals have isolated their slice of the metropolitan pie. Hospital supported paramedical personnel can be trained to check blood pressures, do well baby exams and run various patient instruction programs. These varied and valuable programs do provide a community service while at the same time they attract patients to the hospital. Beds must be kept full to justify overbuilding.

Making your services known is all you have to do if there is a real "unmet health need" in an area. Knocking on doors in a high rise or taking a patient by the hand and bringing him to the hospital is too much like Marcus Welby. It is patronizing and demeaning. Individual patients cannot be spoon fed their medical care. They must take some initiative and responsibility in seeking it out. The time and money devoted to "drumming up business" could better be spent in lowering the cost of, or improving the provision of the acute services that have made our hospitals the best in the world.

Each of the elements of care have their sphere of influence, their thing—that which they do best. Complete, comprehensive, continuing cradle-to-grave preventative medicine is not what hospitals do best. Hospitals should limit themselves to that which they do best; provide a place for the provision of sophisticated episodic care at the lowest possible cost.

Any broadening of this focus on acute care is a wasteful duplication of services one of the other elements can do better and cheaper. A hospital cannot be all or do all things for all people. Its resources, though immense, are finite and must be conserved and concentrated. A hospital is a thing to be avoided. It belongs on the periphery of the circle of medical care, rather than in the center of the circle radiating its expensive services in the community outreach programs.

These programs, instead of lowering the cost for acute care, make the acutely ill patient subsidize the cost of these teaching and outreach programs. They are valuable programs and they need to be done but not by the most expensive element of our delivery system. All this does is encourage more people to use the high priced hospital laboratory and x-ray and clinic facilities rather than the more economical services that can be provided in physicians' offices.

Doctors are as guilty as hospitals in teaching their patients to think of the hospital as the center of the "medical care" system. We are guilty not just on weekends and evenings when we direct our patients there for "emergency" services but also during the week when we admit for diagnostic studies that could be done more cheaply and efficiently in our offices.

Each hospital Executive Committee should instruct the Long Range Planning Committee of their Board of Trustees that hospitals can better serve their communities by improving or lowering the cost of acute care services than they can by trying to provide a complete package of care.

Each hospital Executive Committee should carefully consider all additional steps taken in the direction of expanding rather than concentrating services; for the costs are additive and the consequences are geometric with ever widening competing and conflicting concentric circles of comprehensive care.

John E. Smith, M.D.
Minneapolis, Minnesota

IT'S THE LAW

Judgment for Failure of Bone Implantation

The patient sustained a lower back injury in an automobile accident and underwent a laminectomy of L4 and L5 vertebra. A spinal fusion was performed. In performing the surgery, the surgeon used as a grafting material, a product known as Bo-Plant.

The back pain continued and three years later, at the time of a second operation, the Bo-Plant had been partly reabsorbed and had to be removed.

The patient brought action against the drug company supplying Bo-Plant. He claimed negligence, breach of implied and expressed warranty and fraud.

Bo-Plant was made by processing bone from an unborn calf. Clinical studies showed the implantation to be 85-95% successful and the material had been approved by the Food and Drug Administration.

The drug company contended that the patient did not prove that the Bo-Plant used in the patient's operation was defective. The court said that it must clearly prove that there was an actual adulteration of the product in order for the company to be liable for harm resulting from its use. The court found that there was no evidence to support a finding that the drug company ignored, concealed or suppressed adverse medical reports concerning failures experienced in the use of its product. The court found that the company was not guilty of breach of implied warranty, negligence or fraud.

Bronchopulmonary Dysplasia in a Premature Exacerbated by Oxygen Therapy

for
Pneumomediastinum and Pneumothorax

MARTHA BURKE-STRICKLAND, M.D.* and CHARLES A. ROGERS, M.D.†

HIGH AMBIENT OXYGEN has been used to facilitate removal of loculated air in the chest of newborns.¹⁻³ The need for caution in using this method of treatment in prematures because of their vulnerability to retrolental fibroplasia is well recognized.^{1,3} The following case suggests that caution is also needed in the use of high ambient oxygen for therapy of pneumothorax and pneumomediastinum in an infant at risk from bronchopulmonary dysplasia (BPD).

Case Report

A 1,400 gram infant was born at 30 weeks gestation by breech delivery to a 20-year-old primigravida. Spontaneous vaginal bleeding secondary to marginal sinus rupture heralded the onset of the five hour labor. The one minute Apgar score was two. When the baby did not respond to assistance with a positive pressure mask and 40% oxygen, she was intubated and given direct ventilatory assistance per endotracheal tube. The five minute Apgar score was eight. She was extubated and transferred to the newborn intensive care unit in a warmed transport incubator. One-half hour after birth, while on 30% oxygen, her blood pH was 7.33, pCO₂ 49 mm Hg, and pO₂ 110 mm Hg. Increasing tachypnea, grunting, and changes in the chest Xray over the next 48 hours were consistent with moderate respiratory distress syndrome (RDS). By 72 hours of age, the baby required 60-70% oxygen to maintain an arterial pH of 7.3 and a pO₂ between 50 and 100 mm Hg. This ambient oxygen concentration was continued for 34 hours. She did not require any other ventilatory assistance and the expected resolution of the RDS began on the fifth day. A chest Xray at that time showed possible early bronchopulmonary dysplasia. By the tenth day she was able to tolerate room air. Her color was pink. Respirations were stable and easy at 60-70 per minute though she still

had occasional sternal retractions. On the twelfth day, increasing duskiness and dyspnea prompted reinstitution of oxygen therapy. A chest Xray revealed moderate pneumomediastinum. Initially her cyanosis was relieved by 35% oxygen but later in the evening she began having repeated episodes of apnea accompanied by bradycardia. Re-Xray showed increase in the pneumomediastinum and extension to a right pneumothorax.

Fifty minutes of 100% oxygen therapy improved the infant. It was decided that the conservative approach (inhalation of 100% oxygen) would be continued. Twenty hours of continuous 100% O₂ was followed by another three days in which the ambient O₂ ranged from 50-95%. Her measured arterial pO₂'s did not exceed 104 mm Hg.

By the seventeenth day, after four days of high ambient oxygen, the pneumomediastinum and pneumothorax were resolved but the infant still required 25% ambient oxygen to maintain satisfactory blood gases and pH. On the 19th day, she again experienced increased retractions, tachypnea, and cyanosis which required 50% oxygen for relief. Xrays did not show any recurrence of pneumomediastinum or pneumothorax. Blood and tracheal aspirate cultures were negative.

By the 25th day, linear densities interspersed with fine cystic honeycombing were quite evident on the chest Xray. This was interpreted as further extension of BPD. Cor pulmonale, evidenced by tachycardia, tachypnea, and rapidly increasing liver size, responded well to digitalization. Supportive nebulization, physiotherapy, and antibiotics were continued for three weeks. She was gradually able to tolerate room air again.

She was discharged on Lanoxin at age two months weighing 3,010 grams. Her respirations were comfortable with slight retractions at 50 per minute. The chest Xray still showed increased linear densities fanning out from hilar areas into lateral portions of lung parenchyma. Scattered fine flocculent areas of increased density were also present. This was interpreted as residual BPD. Her arterial pH was 7.44 and the pCO₂ 29 mm Hg and pO₂ 63 mm Hg on room air. Lanoxin was discontinued at a two weeks follow up visit. At one year of age the child appeared clinically well. There was no evidence of retrolental fibroplasia and the chest Xray showed marked improvement with only faint linear densi-

*Formerly: Assistant Professor of Pediatrics, University of Minnesota, Director of Newborn Services, Hennepin County General Hospital, Minneapolis, Minnesota.

†Resident in Pediatrics, University of Minnesota, Minneapolis, Minnesota.

ties residual in the parenchyma. After breathing 100% O₂ for 15 minutes, her arterial pO₂ was only 77 mm Hg.

Comments

While risk of retrolental fibroplasia was weighed in the decision to use oxygen therapy in management of the pneumomediastinum and pneumothorax in this infant, the additional risk of bronchopulmonary dysplasia was poorly appreciated at the time. During the treatment period, her arterial pO₂ was not allowed to exceed the limits currently considered acceptable for protection of the premature retina.^{4,5} However, the four day period of high ambient oxygen therapy before resolution of the pneumomediastinum and pneumothorax did exceed the safe limits in terms of oxygen toxicity to the premature lung. Anderson et al. found changes of BPD invariably present in infant lung tissue after 30 hours exposure to high ambient oxygen. Progressive changes were found to occur with increased length of exposure.^{6,7} Clinical recovery with gradual improvement in the damaged lung is known to occur as it did in this case.^{8,9,10,12} However, criteria are not yet established for determining reversibility either generally or for a given infant.

In addition to dose-time relationships of oxygen effect upon the lung, production of BPD appears to be greatest when toxic effects of oxygen are superimposed upon underlying pathology of the lung.⁸⁻¹⁰ While the condition of the newborn most often reported in association with sequelae of oxygen therapy has been RDS, the potential for developing BPD seems to be present in any

respiratory problem of the neonate that requires high ambient oxygen.^{11,12} Since symptomatic pneumomediastinum and pneumothorax are often related to situations that have required vigorous resuscitation,^{13,14} the chances are high that underlying lung tissue damage from hypoxia and acidosis will also be present. The infant may thus be more vulnerable to BPD if 100% oxygen therapy is employed to facilitate removal of loculated gases from the chest. Alternative therapy, aspiration or closed chest drainage, also carries some risk. Srouji found increased survival in those treated with thoracostomy compared with those who had only medical treatment.² This infant did survive but hospitalization was prolonged beyond the time expected for prematurity and mild to moderate RDS alone. Probably some compromise of lung function resulted from the initial RDS and oxygen therapy but there is little doubt that the extra four days of high ambient oxygen made the loss more severe. In retrospect, it was felt that aspiration or tube thoracostomy probably would have relieved the symptoms more promptly and shortened the need for increased ambient oxygen therapy.

Since it is not yet known at which point the effects of oxygen toxicity may still be reversible and when they are not, it would seem reasonable to avoid this risk for the premature whenever possible. It is suggested that aspiration or closed chest drainage may be better choices than the use of 100% oxygen for the relief of symptomatic pneumothorax and pneumomediastinum in the premature infant.

First Trimester Abortion*

JANE E. HODGSON, M.D.[†] and KATHEY C. PORTMAN, B.A.

A SURGE OF ACTIVITY is evident around the country among members of the medical professions in an attempt to implement the new abortion laws. It is important that the facts regarding the proper techniques, settings, and complications be presented in a straight-forward manner.

We would like to emphasize where, when, and how pregnancy terminations should be performed and to discuss the complications of first trimester procedures in some detail as well.

Where should first trimester pregnancy terminations be performed? We view the free-standing clinic now as the main source of delivery of this highly specialized procedure. The free-standing clinic can terminate first trimester pregnancies far more economically and expeditiously than the usual hospital. Treatment can be individualized and humanized more readily in a free-standing clinic than in the impersonal and highly regimented hospital.

There is a great struggle going on between two factions in many hospitals as to whether or not the procedure will even be done. Problems concerning the personal objections of the physicians and para-medical personnel are constantly arising. The patient will suffer if some of the hospital staff view the procedure with disapproval. Sympathy and empathy are obvious requisites of humane medical services.

It is also obvious that a wide-spread effort must be made to reduce costs of medical care. With pre-admission screening, and hospital review committees, many hospital procedures will soon be assigned for out-patient treatment, regardless of insurance coverage. This is the only way that the high cost of medical service will be curtailed. Free-standing abortion clinics are pioneering the way for delivery of many surgical and medical services on an out-patient basis.

When is pregnancy termination best performed?

Terminations should be performed during the first trimester prior to the 12th week after the last menstrual period (LMP—10 weeks gestation). This is the most important single factor in reducing complication rates.

A great effort must be made by the medical profession to emphasize the lower complication rates in first trimester abortion and to educate the public, particularly the young teen-ager. Evidence of success in this effort is the fact that 85% of pregnancy terminations done in New York at the present time are performed in the first trimester.¹ At Preterm Clinic, Washington, D.C., 50% of our terminations are done on patients that are eight weeks LMP or less.

How should first trimester pregnancies be terminated? Vacuum aspiration under local anesthesia has proven the safest technique. There is very little place for D&C under general anesthesia.

Free-standing abortion clinics have well demonstrated the increased safety and economy of vacuum aspirations done on an out-patient basis under local anesthesia with "no-touch" technique.²⁻⁵ The importance of integrating this service with counseling, contraceptive services, and sterilization has been emphasized.² Local anesthesia permits the blending of the surgical procedure with the entire counseling process.

Procedure

In the successful "model" clinics^{2,5} the patient, previously registered by telephone, is present in the facility for an average three to four hours. The history is taken, followed by a physical examination to confirm the duration of the pregnancy and to rule out any medical complications which might be a contra-indication for an out-patient procedure. Laboratory studies include Rh typing, hematocrit, urinalysis, cervical cultures for gonorrhea, and tests for ferning of cervical mucus and pregnancy. After a one-to-one counseling period, termination is performed. The counselor accompanies the patient through the entire procedure, which is performed under a

*Presented at the 120th Annual Meeting of the Minnesota State Medical Association, Minneapolis, Minnesota, 25 May 1973.
[†]Medical Director, Preterm, Washington, D.C.

paracervical block (1% lidocaine). No perineal "prepping" is done, nor are sterile drapes employed. Operators use sterile gloves during cervical dilatation and uterine evacuation. No unsterile object is allowed to enter the uterine cavity. The "soft" technique using flexible cannulas (Karman) is usually employed when pregnancy is less than eight weeks LMP. Minimal cervical dilatation is performed with the least possible force by use of the Pratt dilators, which are far superior to the more commonly known Hegar dilators.

Rh₀ (D) Immune Globulin (Human) is administered when indicated. Contraceptive devices are supplied at this time, and the patient is taken to the recovery area. It is rarely necessary to keep the patient more than an hour.

Complications

And what are the complication rates which follow such a radical departure from our conventional surgical routines?

When we talk about complications following pregnancy terminations, it is necessary to define our terms. We must consider:

1. The stage of gestation, and
2. The method of termination (which varies with each trimester).

In the first trimester, the method is usually vacuum aspiration, or a D&C under general anesthesia. The latter has a higher complication rate than vacuum aspiration. For the second trimester, during which a procedure carries a three to five times higher risk than the first trimester, the technique used may be vacuum aspiration (up to the 14th week) followed by either saline induction or hysterotomy. Dr. Tietze's most recent figures on the incidence of the various types of procedures in 1972 in New York's women resident patients were as follows¹:

Suction Aspiration	67.0%
D&C	15.5%
Saline	12.0%
Hysterotomy	0.8%

The mortality rates of the above procedures were recently given by Dr. Jean Pakter of the New York City Health Department based upon the New York City experience⁶:

Pregnancy Termination.	
all methods	4.0 deaths/100,000
Vacuum Aspiration	0.4 deaths/100,000*

*There was one death following vacuum aspiration in the first year of legalized abortion (July 1970-July 1971), and no deaths occurred in the second year (July 1971-July 1972).

D&C	2.5 deaths/100,000
Saline	16.5 deaths/100,000
Hysterotomy	222.8 deaths/100,000

We must further classify complications as to the time when they occurred, namely whether they were:

Pre-existing Complications: An example of pre-existing complication is the fact that between .5 to 1% of our patients have positive gonorrhea cultures. These women are asymptomatic, but one would expect that a patient with a positive gonorrhea culture would be more inclined to develop a severe complication. Interestingly, this group has been remarkably free of any postoperative problems and convalescence has been smooth. Other examples of pre-existing complications would be congenital uterine anomalies, ectopic pregnancies, hydatidiform moles, and latent pelvic infection.

Immediate Complications: The immediate complications are uterine perforation, hemorrhage, anesthetic reactions, and also cervical lacerations. These are diagnosed at the time of the procedure and studies of incidence rates of immediate complications should not be affected by any lack of proper follow-up studies.

Early Complications: Except for the immediate complications, abortion patients rarely have any serious problems for two to three days. If hospitalization is required, it is rarely sought before two or three days after the initial procedure. The commonest early complication is retention of secundal tissue, causing the well-known triad of symptoms, bleeding, fever, and pain. Many patients will respond to antibiotics and do not require the additional trauma of re-evacuation.

Delayed Complications: A fourth type of complication is the delayed or latent type, the incidence of which we are rather uncertain at the present time. We have not had legalized abortion in this country for a long enough period of time to study the women who have had procedures done under the proper circumstances. There is a trend at this time to deplore the possibility of delayed late complications.⁷ Obviously, there has not been enough time in this country to develop statistics on any so-called delayed complications, such as premature labor in subsequent pregnancies, increased spontaneous abortion, increased premature labor, ectopic pregnancies, and various other pregnancy accidents. In order to compute delayed complications, it has been necessary to

FIRST TRIMESTER ABORTION

ely on retrospective studies rather than prospective studies. The latter are obviously much more accurate, but will take a number of years to complete.

The late complications of other countries have also been quoted at length, chiefly those from England.⁷⁻⁹ The English primarily use the D&C method with general anesthesia, largely because of their law requiring a 24-hour hospitalization, which discourages the use of local anesthesia and vacuum aspiration on an "in-and-out" basis. We know that when the abortion is performed under general anesthesia, with the old D&C method, there is usually greater cervical dilatation, increased bleeding, and a higher complication rate. Furthermore, some of the studies that have come out of England have included some second trimester abortions as well as first and have not made a clear-cut distinction between the two. There is obviously a considerable difference in the degree of cervical dilatation which is necessary in the early first trimester with the use of a Karman cannula as compared to the cervical dila-

tation required with a 14-week pregnancy, performed under general anesthesia. These are not comparable procedures and their complications cannot be compared.¹⁰

Tables 1, 2, and 3 show the complications that were incurred during three different months during the past year at Preterm. These months were picked at random after sufficient time had elapsed to obtain an adequate follow-up. By urging patients to make collect phone calls to us on a 24-hour basis, by supplying follow-up forms for both patients and physicians, as well as providing a follow-up clinic, we maintain a patient follow-up of approximately 70%. Table 4 shows the total complications for the three months with the total incidence rate of major and minor complications.

Dr. Tietze⁴ defines major complications as follows:

"Major complications include unintended major

surgery, one or more blood transfusions, three or more days of fever, over one week hospitalization, and other categories associated with comparable degrees of risk of death, prolonged illness or functional impairment." In Tables 1, 2, 3, and 4 all major complications were, of course, listed, as well as any cases that were hospitalized for any reason whatsoever within the immediate post-operative period. The minor complications are chiefly patient's complaints of cramps, mild fever, or bleeding problems, none of which required hospitalization. Loop complications are also included in this category.

June is a rather typical month (Table 1), except for a higher than usual perforation rate. There was a total of three perforations, two of which were treated conservatively, and one of which was laparotomized and the perforation repaired. The only other surgical case occurred in October (Table 2) being listed as "subsequent surgery (salpingectomy)" and is deserving of explanation. This was a patient with a previous history of a tubal pregnancy for which unilateral salpingectomy had been performed. At the time of the vacuum aspiration, the pregnancy was extremely early, tissue was minimal, and the operator could not grossly recognize chorionic villi. The patient was warned regarding the possibility of an ectopic pregnancy in the remaining tube and was told that she would be called regarding the pathologist's report. We learned later that in less than 48 hours, her remaining tube was inadvertently removed by an outside physician, who would not wait for the pathology report which did describe chorionic villi.

Perforation

Fear of uterine perforations haunts every operator. This most serious complication should be suspected: (1) when no tissue is obtained with aspiration, (2) when dilatation has been unusually difficult, (3) when instrument penetration is deeper than size of uterus and (4) when there is sudden, severe pain. This latter diagnostic aid is another advantage of para-cervical block over general anesthesia. Dr. Nathanson has recently pointed out the strong correlation between uterine retroversion and perforation.¹¹ This relationship was corroborated in our three-month study. With a total of six perforations, in four cases the uterus was retroverted.

Immediate treatment consists in starting intravenous fluids to which pitocin may be added,

continual monitoring of the vital signs, frequent checking of the abdomen for signs of intraperitoneal bleeding, and possible transfer to the hospital. It is preferable that the diagnosis be confirmed by another physician. Where there is an question of damage to the bowel, as for example omentum appearing in the cannula, laparotomy should be performed immediately. When perforation is suspected, suction should obviously never be used subsequently because of the danger of the suction tip traumatizing the bowel or mesentery. If evacuation has to be done following a uterine perforation, a curette should be used instead of suction.

In the past 14 months, at Preterm Clinic over 18,000 procedures have been performed. We have had a total of 17 suspected perforations, which makes an incidence of roughly one per 1000 procedures. Two of these were actually pelvic infections diagnosed as possible perforations several days after leaving our care. They were inadvertently explored and no perforations were found. Two other cases were diagnosed during the procedure at Preterm Clinic and were immediately transferred, explored, and repaired. Only four out of the 17 required surgery, which fact probably reflects the early stage of gestation in most of our patients. The fact that almost 50% of our cases are eight weeks LMP or less increases the possibility of treating this complication conservatively.

Re-Evacuation

Re-evacuation is probably the commonest complication of first trimester pregnancy termination and is usually done because of retention of secundines. Herein are grouped most of the complications, characterized by the symptom triad of fever, bleeding, and pain. The number that are hospitalized depends somewhat on the attitude of the doctors giving the follow-up care. It has been apparent that, as the attitude has changed towards abortion procedures and physicians have become more familiar with abortion complications, they are more willing to treat post-abortion complications on an ambulatory basis. The incidence of re-evacuation also reflects the experience of the operator. It has been apparent that the re-evacuation rate increases when new physicians are taken onto the staff.

Most cases of hemorrhage fall into this group. As a rule, very little blood is lost with the vacuum aspiration procedure itself, and the bleeding due

to retained tissue usually does not occur for several days after the procedure. There were three transfusions given to the 4,036 patients treated by us during the three-month period studied. Each of the three patients received two pints of blood, but not until several days after the procedure. Retention of tissue was involved in each of the three cases. At no time in our experience at Preterm has any patient required blood within the first 24 hours after the procedure. This does not mean that a catastrophic hemorrhage could not occur, but after 28,000 procedures with only delayed types of bleeding, it is safe to say that immediate hemorrhage is far from common.

Unsuccessful Termination or Continuing Pregnancy

Into this category fall the cases that were discontinued because of the patient's low threshold for pain, an expression of preference for general anesthesia, difficulty in dilatation of the cervix, and so forth. In most of these instances, the failure is obvious and it is simple to transfer the patient to the hospital where the procedure can be done without difficulty. In the case of difficult cervical dilatation, if the pregnancy is an early one, the patient may be advised to return at a later date, at which time cervical dilatation is usually accomplished with ease. The obvious termination failures are no problem. It is the unsuspected ones that are embarrassing and often tragic. In these situations, pregnancy continues in spite of an apparently normal evacuation, and we are informed of this fact several weeks or months after the initial procedure. Continuing pregnancy has occurred to our knowledge four times in the past 18,000 procedures. In each of the four instances mentioned, a double uterus was excluded. Two patients required a saline induction at 16 weeks, one delivered spontaneously at 16 weeks, and the fourth patient had a vacuum aspiration performed in the hospital at 14 weeks.

This unfortunate complication occurs more frequently in the very early pregnancies, where the small cannulas are used, such as #4 and #5 Karman cannulas. Dr. Stim¹² reports a 5% incidence of missed pregnancies when a #4 Karman cannula was used. He noted a .7% incidence of missed pregnancy with a #5 Karman cannula. Apparently it is possible in early pregnancy to miss the implantation site during aspiration and the pregnancy continues to develop. Therefore, it is extremely important that the tissue be carefully

examined, and sent to the laboratory if chorionic villi cannot be grossly identified, or whenever the tissue is extremely scanty in amount. If there is any question as to the actual termination of pregnancy, the patient should be followed with repeat pregnancy tests, particularly if there is very little or no bleeding following the procedure. It is extremely important that these patients do not become lost to follow-up and pass into a later stage of pregnancy.

Mis-Estimation of Gestational Duration

In spite of competent screeners, and second pelvic examinations by the physician prior to each procedure, occasionally a termination will be begun before the operator realizes that the pregnancy is too far advanced for the vacuum aspiration method. If the uterus sounds beyond 14 cm, the operator should stop and re-evaluate the situation. The pregnancy is either more than 14 weeks, or the uterus is enlarged enough to necessitate being done in another setting. The patient can be moved to the hospital if nothing has been done other than the sounding of the uterus. Active bleeding is rare in this situation. However, bleeding, fever, or labor can ensue shortly thereafter, so it is wise not to delay in transfer of the patient. Another sign that the pregnancy is too far advanced is excessive amniotic fluid. By the time this is noted as it passes through the tubing, the wiser course may be to continue with the procedure. After starting intravenous fluids to which oxytocics should be added, it may be necessary to further dilate the cervix to enable the use of a 14 mm cannula. Fetal parts should be carefully identified to be sure of complete uterine evacuation. It may be necessary to remove fetal parts individually with the intra-uterine dressing or ovum forceps if the tissue is too large in amount to go through the cannula. Obviously, I speak of this situation only to condemn it, and hope none of you will ever be caught in such a predicament. It is up to the judgment of the operator in such a situation to decide whether it is better to transfer the patient immediately or to attempt to complete the procedure at the clinic. Three such transfers have been necessary in the past year.

Ectopic Pregnancies

If no villi or fetal parts are visible in a scanty tissue specimen, and the possibility of perforation is ruled out, the operator should then consider the possibility of an ectopic pregnancy. The tissue must be sent to the laboratory, preferably for a

frozen section, and adnexal masses or tenderness should be noted. The patient is warned of the possibility of an ectopic pregnancy, and she and her physician are notified of the pathologist's report. In very early pregnancy, diagnosis of an ectopic pregnancy may be extremely difficult, and the patient must be followed carefully with pregnancy tests, pelvic examinations, laparoscopy or culdoscopy.

Cervical Lacerations

Cervical laceration is commonly mentioned as a complication of the abortion procedure, but we have had very few. The proper technique and choice of instruments in dilatation of the cervix is probably responsible for our elimination of this troublesome complication. An extremely deep bite is taken with a single-toothed seven-inch Barrett tenaculum through the cervical canal at 12 o'clock, with one prong of the tenaculum actually inside the cervical canal. Dilatation is then carried out using as little force as possible. A more gradual, less forcible dilatation process is possible by using Pratt dilators instead of the well-known Hegar dilators commonly used in hospitals. The Pratt dilator is more tapered at its end and an increased number of instruments in the set allows for a more gradual dilatation process. The use of 20 cc of 1% lidocaine in administering the paracervical block also facilitates dilatation. No great force should be required, and if the ordinary uterine sound cannot be made to enter the cervical canal, a small four or five millimeter flexible cannula is used. If there is any marked abnormality of the cervix, the procedure should be done in the hospital setting.

Summary

Out of a total of 4,036 procedures performed during a three-month period, there was a total significant complication rate of 1% or 41. Minor complications totalled 94, an incidence of 2.3%. There were six perforations out of 4,036, making an incidence of 1.5 per 1000 cases or 0.15%. In the last 18,000 patients we have a total of 17

suspected perforations, which gives a slightly lower incidence of 1 per 1000 (0.10%).

The total number of re-evacuations was 18 in 4,036 procedures, an incidence of 4.5 per 1000 (0.45%). There were an additional seven patients hospitalized with pelvic infections. There were two unsuccessful terminations, one suicide attempt, two hydatidiform moles, two underestimations of duration or gestation, and two ectopic pregnancies.*

Except for one woman who was hospitalized for ten days, none of these patients were hospitalized for more than a week.

Conclusions

Now that, at long last, we have obtained for women the right to a safe and low-cost abortion, what else are we as physicians obligated to do? We must instill social responsibility into our youth by improving their sex education. It must be taught to them that parenthood is an awesome privilege, not necessarily a right. A sexually active woman should feel a responsibility to use an effective method of contraception. Contraceptive services and pregnancy diagnosis should be available to every woman of every age group and the effectiveness of the various contraceptive methods should be well-known.

Abortion is to be condemned as the sole method of contraception, and it should serve only as a necessary back-stop for contraceptive failure. If pregnancy termination is determined necessary, safe, low-cost abortion should be available to any woman of any age in her own locality, and the service should be rendered with dignity and without moral judgment.

The public should *know* that, at the present time, the least expensive, safest, most expeditious site for the delivery of abortion services is the free-standing clinic rather than the hospital or the doctor's office. Contraceptive counseling should be mandatory at the time of the abortion procedure. Women should *know* that the earlier the pregnancy, the safer the termination. Doctors should *know* that local anesthesia with vacuum aspiration is the safest method of termination. By these means, our many problems related to reproduction may be better treated and controlled.

*Since the preparation of this article, an additional ectopic pregnancy as well as another suicide attempt have been reported for the month of January 1973.

Banana-Flavored Donnagel® PG

The civilized solution to the age-old problem of diarrhea.

The evolution of Donnagel® PG:

Kaolin and pectin to provide demulcent-detoxicant effects.

Belladonna alkaloids for antispasmodic benefits.

Powdered opium, the therapeutic equivalent of paregoric—without the unpleasant taste—to promote the production of formed stools and lessen the urge.

And a delicious banana flavor good enough for the most discriminating tastes.

All together in the evolutionary discovery that's the best-tasting way yet to treat acute, non-specific diarrheas.

Donnagel® PG

Donnagel with paregoric equivalent.

Each 30cc. contains:

Kaolin	6.0 g.
Pectin.	142.8 mg.
Hyoscyamine sulfate	0.1037 mg.
Atropine sulfate	0.0194 mg.
Hyoscine hydrobromide	0.0065 mg.
Powdered opium, USP.	24.0 mg.
(equivalent to paregoric 6 ml.)	
(warning: may be habit forming)	

Sodium benzoate

(preservative). 60.0 mg.

Alcohol, 5%

Ⓒ Available on oral prescription or without prescription in compliance with applicable state and local law.

A·H·ROBINS

WINTER COUGHS

CLEAR THE TRACT WITH THE ROBITUSSIN[®] LINE

The coughing season is here again. Time to rely on the four Robitussins and Cough Calmers to help clear the lower respiratory tract. All contain glyceryl guaiacolate, the efficient expectorant that works systemically to help increase the output of lower respiratory tract fluid. The enhanced flow of less viscid secretions soothes the tracheobronchial mucosa, promotes ciliary action, and makes thick, inspissated mucus less viscid and easier to raise. Available on your prescription or recommendation.

For coughs of colds and "flu"

ROBITUSSIN[®]

Each 5 cc. contains:

Glyceryl guaiacolate 100 mg.
Alcohol, 3.5%

For unproductive allergic coughs

ROBITUSSIN A-C[®]

Each 5 cc. contains:

Glyceryl guaiacolate 100 mg.
Pheniramine maleate 7.5 mg.
Codeine phosphate 10.0 mg.
(warning: may be habit forming)
Alcohol, 3.5%

Non-narcotic for 6-8 hr. cough control

ROBITUSSIN-DM[®]

Each 5 cc. contains:

Glyceryl guaiacolate 100 mg.
Dextromethorphan hydrobromide 15 mg.
Alcohol, 1.4%

Robitussin-DM in solid form for "coughs on the go"

COUGH CALMERS[®]

Each Cough Calmer contains:

Glyceryl guaiacolate 50 mg.
Dextromethorphan hydrobromide 7.5 mg.

Relieves cough, clears sinuses and nasal passages—keeps them "drip-dry" but not bone dry

ROBITUSSIN-PE[®]

Each 5 cc. contains:

Glyceryl guaiacolate 100 mg.
Phenylephrine hydrochloride 10 mg.
Alcohol, 1.4%

Robitussin[®]

Left Upper Quadrant Pain

R. J. CAMPAIGNE, M.D.,* J. J. COLL, M.D.,* F. L. JOHNSON, M.D.,*
and J. M. STREITZ, M.D.*

A 56-YEAR-OLD WHITE male was admitted to St. Luke's Hospital, Duluth, July 8, 1971, with a two-month history of left upper quadrant pain. The distress was persistent in nature and aggravated by manual labor. There had been no weight loss or change in bowel characteristics and his previous health had been excellent. Symptoms of early obstructive lung disease were presented. The patient complained of pain in the left upper quadrant that was intensified with abdominal palpation and deep inspiration. A mass could not be delineated. Blood pressure examination was 132/86. The remaining portion of the physical examination was within normal limits.

Laboratory studies: Hgb. was 12.5 gm.%, WBC 7,900 with a normal differential. A urinalysis was normal. Sedimentation rate 34 mm/hr. The blood chemistry profile was normal with the exception of an elevation of LDH to 175 units (normal for lab.). Blood gases (O_2 , CO_2 , PCO_2) were normal as was an arterial pH. Pulmonary function studies were compatible with a moderate degree of pulmonary emphysema. A 24-hour urine creatinine level was normal, though the 17 hydroxy and 17 keto steroids were slightly elevated, 14 mgm. and 30.8 mgm. respectively. A dexamethasone suppression study (2 mgm. orally q6h X 8 doses) revealed a complete suppression of the plasma cortisol levels. A urinary catecholamine level was 49 mcg/24 hrs. (within normal limits). Serum electrolyte studies were normal.

A chest Xray was normal. An intravenous pyelogram revealed a downward and outward displacement of the left kidney, confirmed by retrograde pyelogram. A selective arteriogram via the left femoral artery demonstrated a 10 x 15 cm. mass in the region of the left adrenal gland with calcification, (Figure 1) suggestive of adrenal tumor.

Eight days following admission, the patient was taken to surgery where a large encapsulated

adrenal tumor was removed. An incidental splenectomy was also performed to obtain adequate exposure of the tumor. Five units of whole blood were given. The patient made an uneventful recovery and was discharged eleven days post-operatively.

Pathology

Gross description left adrenal gland (Figure 2): This is an encapsulated tumor which weighs 865 grams. It measures 15 by 15 by 10 cm. On the cut section there is a uniform pinkish tan colored tissue recognizable. The center of the lesion is exten-

Fig. 1—Femoral arteriogram demonstrating a mass in the adrenal area.

*Duluth, Minnesota.

Fig. 2—Pathological specimen.

sively necrotic. The tissue is soft and friable. Representative sections from different areas are taken for microscopic examination.

Microscopic: Selected areas of the grossly observed tumor reveal eosinophilic cells with focal areas of foam cell formation. A moderate variation in size and staining property of the nuclei is seen, and an occasional area of giant cell formation is found. These reveal a prominent variation in size and configuration of the nuclei. Careful search, however, does not show any evidence of vascular invasion of the lesion, and no prominent mitosis. Prominent areas of necrosis are found within the tumor.

Diagnosis: Adrenal cortical tumor, benign.

Discussion

Tumors of the adrenal gland have been classified according to Ackermann as follows:

1. Cortical tumors
 - A. Adenoma
 1. Functioning

2. Nonfunctioning

- B. Adrenocarcinoma

2. Tumors arising from the medulla

- A. Ganglioneuroma

- B. Pheochromocytoma

- C. Neuroblastoma

- D. Mixed variety (ganglioneuroblastoma etc.)

Preoperatively, it was thought the tumor in question was a large nonfunctioning cortical adenoma as substantiated by the laboratory data. There was only a slight elevation of the urinary 17-keto and 17-hydroxy steroids with a dramatic suppression of cortical blood levels with the oral dexamethasone study. The urinary catecholamines were normal, as were plasma electrolyte studies.

Adrenal cortical adenomas are benign encapsulated neoplasms composed principally of cells resembling the adrenal cortex. They are usually single and may reach mammoth size from 1900 grams to 4200 grams. The larger tumors are seen more frequently in the adult, more often on the left. Earlier in life, adenomas are more frequent in females though the difference is not as great in the adult. The functioning adenoma is also more frequent in the younger individual. The overall clinical manifestations depend upon 1. size, position, 2. hormone production, 3. and resultant metabolic disturbances. The larger adenomas may demonstrate malignant change as seen by blood vessel invasion, though the true test of malignant change is the passage of time and the absence of metastasis.

Pseudo-Banti's Syndrome

This term is sometimes used to describe a typical Banti's syndrome that is caused by syphilis. Curschman has reported the case history of a patient who had hepatic cirrhosis, ascites, and esophageal varices.* The patient also had acquired syphilis, which was substantiated by a positive serology. Appropriate antisyphilitic therapy resulted in complete recovery without splenectomy. Curschman emphasizes that a diagnosis of true Banti's syndrome should not be made until the possibility of syphilitic involvement has been excluded; otherwise an unnecessary splenectomy may be done.

MERPHENE®

DISINFECTANT CONCENTRATE

ODORLESS
COLORLESS
EFFECTIVE

MERPHENE is a unique triple formulation of disinfectants, scientifically tested to protect your surgical-dental instruments and equipment.

EASY PREPARATION

Fill a container with a gallon of potable water, add 40cc MERPHENE CONCENTRATE and mix thoroughly. For a quart use 10cc MERPHENE CONCENTRATE.

QUICK KILL POWER

"Use" solution kills *Pseudomonas aeruginosa*, *Staphylococcus aureus*, and *Salmonella choleraesuis* in 10 minutes.

NOT CORROSIVE

A "built-in" rust inhibitor prevents rusting of surgical instruments, needles and syringes. Rubber, plastic appliances, masks and first-aid pieces are not affected.

Does not contain Mercury, Phenol, Alcohol, Iodine, Phosphates or Hexachlorophene. Stability is high and it is non-volatile. It is compatible with Alcohol, Acetone, Glycerin and water. It is incompatible with soap and aluminum. Detergency is excellent and it deodorizes as it cleans.

LESS STORAGE SPACE,

yet permits larger volumes on demand.

ECONOMICAL:

per gallon cost, way under competition.

Classified advertising rates are thirty (30) cents a word; minimum monthly charge \$7.50; key number, fifty (50) cents additional.

Replies to advertisements with key numbers should be mailed in care of Minnesota Medicine, 375 Jackson, St. Paul, Minn. 55101.

COUNTRY LIVING-METROPOLITAN CONVENIENCE—WANTED AND NEEDED: One or two General Practitioners to set up practice in new and equipped clinic with utilities paid and rent free 6-12 months. Service area of 9,000 and rapidly growing. New hospital in planning stages, new high school under construction. Located within one hour of Minneapolis-St. Paul. Dental, Veterinary, and Mental Health Clinics also located here. Golfing, bowling, fishing, hunting, etc. in area. Interview expenses and all moving expenses paid. Join us for comfortable country living with big city benefits. Try it, you'll like it! Write: MINNESOTA MEDICINE—485, 375 Jackson, St. Paul 55101.

A BETTER PLACE TO PRACTICE MEDICINE. For those who would prefer to live in a warmer climate, avoid the big city school, traffic and practice problems; contact this multi-specialty group, located in a city of 100,000 people in North Central Texas. Specialists in Internal Medicine, Family Practice, Pediatrics, General and Orthopedic Surgery are needed to complement the current staff of twenty-one full time physicians. Wichita Falls Clinic-Hospital, 1300 Eighth, Wichita Falls, Texas 76301.

WANTED—Recently trained radiologist to provide modern diagnostic and therapeutic radiological services for a recently consolidated midwest regional hospital of approximately 300 beds. Radiologist recently expired and his part time associate plans to retire soon. Write: MINNESOTA MEDICINE—492, 375 Jackson, St. Paul 55101.

FAMILY PHYSICIANS needed in the community of Tracy, Minn. New clinic being built to accommodate 4 doctors in a clinic setting. Excellent opportunity. Contact Administrator, Tracy Municipal Hospital, Tracy, Minnesota 56175, phone 507-629-3200.

PHYSICIANS ASSISTANT—Graduate University Washington MEDEX program. Three years Special Forces medic, one year with GP. Resume upon request. Michael Erkel, Route 2, Box 142, Kimberly, Idaho.

IVERS EDGE MEDICAL CLINIC—Farmington, Mn. needs two additional General Practitioners to practice in a nearly new Clinic, Hospital and Nursing Home. Fast growing area just 45 minutes from St. Paul-Minneapolis. Metropolitan advantage with Community living. Contact M. H. Hunter, M.D. (612) 463-7181.

XPANDING TEN MAN FAMILY PRACTICE GROUP in southern Minnesota. Seeks GENERAL PRACTITIONER OR INTERNIST for summer of 74. New clinic adjacent to a new 114 bed hospital. Fairmont is a progressive community (City of Five Lakes). Starting salary open, early partnership opportunity. Contact D. E. Grandgenett, Fairmont Medical Clinic. 507-238-4263.

WANTED—General Practitioner for an incorporated practice. Wisconsin community of 6,800 on interstate highways. Excellent schools, recreational facilities. Modern clinic adjacent 85 bed hospital. Salary first year then partnership. Call 608-372-4177 Collect.

HELP—us form 3 to 4 man group. 60 bed new hospital. Resident anesthetist, physiotherapist. County seat and industrial town. Modern clinic facilities. Supreme fishing-hunting close by. Artificial ice arena. Municipal pool and golf course. Shared education and vacation time. Good deal! Drs. Delmore and Metcalf, Roseau, Minnesota 56751.

GENERAL PRACTITIONER desired for northern Minnesota clinic located near Lake of the Woods area. Enjoy the clean air, clear waters, compatible working arrangements including ample time off for meetings, vacations and good financial arrangements. Excellently equipped hospital (acute, skilled nursing and board and care facilities.) fine clinic one block from hospital. Write: Minnesota Medicine, 473, 375 Jackson St., St. Paul 55101.

WAYZATA MEDICAL BUILDING OFFICE SUITES—Located in the fastest growing suburban area in the Twin Cities. We offer:

- Surrounding area of lakes, country clubs, woods, beautiful homes;
- Unsurpassed medical building facilities
- Fast growing area—high median family incomes
- Beautiful building—inside and out
- Inner courtyard with trees and landscaping
- Heated indoor parking
- Adjacent access to freeway system
- Low rental fares—favorable lease terms
- Financial services

We have grown to fourteen specialties since our building was completed two years ago. We particularly are interested in General Practice, Orthopedics, Psychiatry, Urology, Otolaryngology and Internal Medicine. Give us a call. We have a lot more to show you and to talk about. Reply to: Mr. Paske, Wayzata Medical Building, 250 North Central Avenue, Wayzata, Minn. 55391, (612) 473-0031.

WANTED—OBSTETRICIAN-GYNECOLOGIST—Seventeen man multi-specialist group, located in the beautiful Hiawatha Valley, 50 miles south of Minneapolis and St. Paul. Seeks Board Certified or eligible OB-GYN to join present two-man department. Full sharing in delivery and major surgery at once. No pregnancy terminations. Send curriculum vitae and brief background sketch, experience, family data, etc. Write: MINNESOTA MEDICINE—488, 375 Jackson St., St. Paul 55101.

Recommendations[†] on Combination Live Virus Vaccine

American Academy of Pediatrics

Committee on Infectious Diseases

In the September 15, 1971 AAP Newsletter sent to Academy members, the Committee on Infectious Diseases of the American Academy of Pediatrics stated its recommendations on the use of combination live virus vaccines. After a careful review of available data, the committee concluded that:

- "This information indicates that the products are both safe and effective when used as directed."
- The vaccine "...can, therefore, be recommended with the obvious advantages of reduction in the number of injections for any given child and a concomitant decrease in the required visits to a physician's office or clinic."

[†]For complete text of both recommendations see your MSD representative or write to Professional Service Dept., Merck Sharp & Dohme, West Point, Pa. 19486.

United States Public Health Service

Advisory Committee on Immunization Practices

In the April 24, 1971 issue of *Morbidity and Mortality Weekly Report*, the Advisory Committee on Immunization Practices of the United States Public Health Service presented recommendations on the use of combination live virus vaccine. The committee stated that:

- "Data indicate that antibody response to each component of these combined vaccines is comparable with antibody response to the individual vaccines given separately."
- "There is no evidence that severe reactions to the combined products occur more frequently or are more severe than known reactions to individual vaccines (see pertinent ACIP recommendations)."
- "The obvious convenience of giving already selected antigens in combined form should encourage consideration of using these products when appropriate."

M-M-R^{*}

(MEASLES, MUMPS AND RUBELLA
VIRUS VACCINE, LIVE | MSD)

Single-dose vials

M-M-R, given in a single injection, fits easily into your routine immunization program for well babies. Given at age 12 months, M-M-R provides for vaccination early in life against measles, mumps, and rubella.

MSD suggested immunization schedule for well babies

Age	Vaccine(s)
2 months	DPT (diphtheria-pertussis-tetanus) Oral poliomyelitis vaccine (triple)
3 months	DPT ¹
4 months	DPT Oral poliomyelitis vaccine (triple)
6 months	Oral poliomyelitis vaccine (triple)
12 MONTHS	M-M-R (MEASLES, MUMPS AND RUBELLA VIRUS VACCINE, LIVE, MSD)

1. This vaccination may be given at 3 months, 5 months, or at 6 months, depending on your preference or on the condition of the child. Since vaccination with a live virus vaccine may depress the results of a tuberculin test for four weeks or longer, the test and the vaccine should not be given during the same office visit.

^{*}Trademark of Merck & Co., Inc.

For a brief summary of prescribing information, please see following page.

M-M-R

(MEASLES, MUMPS AND RUBELLA VIRUS VACCINE, LIVE | MSD)

Single-dose vials

No untoward reactions peculiar to the combination vaccine (M-M-R) have been reported.

Moderate fever (101-102.9 F) occurs occasionally. High fever (over 103 F) occurs less commonly. On rare occasions, children who develop fever may exhibit febrile convulsions. Rash (usually minimal and without generalized distribution) may occur infrequently.

Since clinical experience with measles, mumps, and rubella virus vaccines given individually indicates that very rarely encephalitis and other nervous system reactions have occurred, such reactions may also occur with M-M-R. A cause and effect relationship, however,

has not been established.

Excretion of the live attenuated rubella virus from the throat has occurred in the majority of susceptible individuals administered the rubella vaccine. There is no definitive evidence to indicate that such virus is contagious to susceptible persons who are in contact with the vaccinated individuals. Consequently, transmission, while accepted as a theoretical possibility, has not been regarded as a significant risk.

Must not be given to women who are pregnant or who might become pregnant within three months following vaccination.

Contraindications: Pregnancy or possibility of pregnancy within three months following vaccination; infants less than one year old; sensitivity to chicken or duck, chicken or duck eggs or feathers, or neomycin; any febrile respiratory illness or other active febrile infection; active untreated tuberculosis; therapy with ACTH, corticosteroids, irradiation, alkylating agents, or antimetabolites; blood dyscrasias, leukemia, lymphomas of any type, or other malignant neoplasms affecting the bone marrow or lymphatic systems; gamma globulin deficiency, i.e., agammaglobulinemia, hypogammaglobulinemia, and dysgammaglobulinemia.

Precautions: Administer subcutaneously; do not give intravenously. Epinephrine should be available for immediate use should an anaphylactoid reaction occur. Should not be given less than one month before or after immunization with other live virus vaccines; vaccination should be deferred for at least six weeks following blood transfusions or administration of more than 0.02 cc immune serum globulin (human) per pound of body weight, or human plasma.

Due caution should be employed in children with a history of febrile convulsions, cerebral injury, or any other condition in which stress due to fever should be avoided. The physician should be alert to the temperature elevation which may occur after vaccination.

Excretion of the live attenuated rubella virus from the throat has occurred in the majority of susceptible individuals administered the rubella vaccine. There is no definitive evidence to indicate that such virus is contagious to susceptible persons who are in contact with the vaccinated individuals. Consequently, transmission, while accepted as a theoretical possibility, has not been regarded as a significant risk.

Attenuated live virus measles and mumps vaccines, given separately, may temporarily depress tuberculin skin sensitivity; therefore, if a tuberculin test is to be done, it should be scheduled before vaccination, to avoid the possibility of a false negative response.

Before reconstitution, refrigerate vaccine at 2-8 C (35.6-46.4 F) and protect from light. Use only diluent supplied to reconstitute vaccine. If not used immediately, return reconstituted vaccine to refrigerator at 2-8 C (35.6-46.4 F), and discard after eight hours.

Adverse Reactions: Fever, rash; mild local reaction such as erythema, induration, tenderness, region lymphadenopathy; parotitis; thrombocytopenia and purpura; allergic reactions such as urticaria; arthritis arthralgia, and polyneuritis.

Occasionally, moderate fever (101-102.9 F); less commonly, high fever (above 103 F); rarely, febrile convulsions.

Encephalitis and other nervous system reactions that have occurred very rarely with the individual vaccine may also occur with the combined vaccine.

Transient arthritis, arthralgia, and polyneuritis are features of natural rubella and vary in frequency and severity with age and sex, being greatest in adult females and least in prepubertal children. Such reactions have been reported with live attenuated rubella virus vaccines. Symptoms relating to joints (pain, swelling, stiffness, etc.) and to peripheral nerves (pain, numbness, tingling, etc.) occurring within approximately two months after immunization should be considered as possibly vaccine related. Symptoms have generally been mild and of no more than three days duration. The incidence in prepubertal children would appear to be less than 1% for reactions that would interfere with normal activity or necessitate medical attention.

How Supplied: Single-dose vials of lyophilized vaccine, containing when reconstituted not less than 1,000 TCID₅₀ (tissue culture infectious doses) of measles virus vaccine, live, attenuated, 5,000 TCID₅₀ of mumps virus vaccine, live, and 1,000 TCID₅₀ of rubella virus vaccine, live, expressed in terms of the assigned titer of the NIH Reference Measles, Mumps, and Rubella Viruses, and approximately 25 mcg neomycin with a disposable syringe containing diluent and fitted with a 25-gauge, 5/8" needle. Also in boxes of 10 single dose vials nested in a pop-out tray with a separate box of 10 diluent-containing syringes.

For more detailed information, consult your MSD representative or see full prescribing information. Merck Sharp & Dohme, Division of Merck & Co., INC., West Point, Pa. 19486

Laboratory Letter

Why the Protein—Bound Iodine (PBI) Test is Becoming Obsolete

The PBI is becoming an obsolete test because of increasing environmental iodine. As documented in this *Letter*, iodine use is now so widespread that half of the high PBIs our laboratory now measures is elevated because of iodine contamination.

It is easy for you to detect grossly contaminated PBIs. But slight iodine contamination is more subtle. The PBI may be just enough to lift the value from the hypothyroid to euthyroid range or from euthyroid to hyperthyroid levels. Just enough, in other words, to deceive you.

Questions and Answers

What are the odds your patient will have a high PBI?

We don't know for sure, but of all the PBIs our laboratory receives about 20 of 100 are elevated.

And what are the chances these elevated PBIs will be contaminated by iodine?

About half of the high PBIs will be contaminated, i.e., the patient has been exposed to enough iodine to elevate the PBI.

Study

I arrived at these figures after studying 100 consecutive patients on whom physicians had ordered a PBI, T-3, and T-4 (Murphy-Pattee).

Twenty of the patients had a high PBI.

After considering the relationships between PBI, T-3, T-4, and thyroid indices (PBI X T-3) and (T-4 X T-3), I concluded:

- 1) Five of the 20 high PBIs were due to hyperthyroidism;
- 2) Five of the 20 high PBIs were secondary to hormones (pregnancy, estrogens, the pill, or other steroids);
- 3) Five of the 20 high PBIs were the result of gross contamination, i.e., the PBIs exceeded 20 mcg.%; and
- 4) Five of the 20 high PBIs were only moderately contaminated, i.e., between eight and 20 mcg.%

PBI and The Rule of Fourths

From these figures from our practice, I have evolved a Rule of Fourths for why a PBI may be elevated:

A *Fourth* of the time, the PBI is high because of hyperthyroidism.

A *Fourth* of the time, the PBI is high because of hormonal factors.

A *Fourth* of the time, the PBI is high because of gross iodine contamination.

A *Fourth* of the time, the PBI is high because of slight iodine contamination.

Why?

Why is iodine contamination so frequent?

Probably because iodine is used to make more products and to do more things that involve more of the people more of the time.

Some examples:

1. *Staples—Food, Bread, and Water*

Did you know agents used to dye foods red contain iodine? Or that Kaboom Oat Cereal has a high iodine content? Were you aware that calcium iodate is used to make ordinary white bread? Or that antibacterial iodine compounds

are employed to purify city water supplies and swimming pool water?

Red-dyed foods, including	Vought, R.L., et al.: Erythrosine: an Adventitious Source of Iodide, <i>J. Clin. Endocrinol. Metab.</i> , 10:747-752, 1972.
Kaboom Oat Cereal	
White Bread	Pittman, J.A., Jr. et al.: Changing Normal Ranges for Thyroidal Radioiodine Intake, <i>N Engl J. Med.</i> , 280:1431-1434, 1969.
Water Supplies	Freund, G. et al.: Effect of Iodinated Water Supplies on Thyroid Function, <i>J. Clin. Endocrinol. Metab.</i> , 6:619-624, 1966.

2. *Drugs—Under and Over the Counter*

Has it come to your attention that iodine contaminates cosmetics, dandruff, medications, antidiarrheal drugs, expectorant mixtures, gargles, suntan lotions, cough medicines, vitamins, Metracal, antiseptic solutions, toothpastes, and vaginal suppositories?

Or have your information sources told you that the FDA has approved Erythrosine—a red dye that accounts for the pink and red hues of these capsules: lithium carbonate, Darvon and Natalins?

Cosmetics	Becker, D.V. and Hurley, O.R.: The Impact of Technology on Clinical Practice in Grave's Disease, <i>Mayo Clin. Pro.</i> , 47:835-847, 1972.
Dandruffs, Cough Mixtures, Gargles, Mouth Washes, and Expectorants	Garb, S.: Clinical Guide to Undesirable Drug Interactions and Interferences, Springer Publishing Co., New York, 1971.
Antidiarrheal Drugs	Ackland, J.D.: Interpretation of Serum Protein Bound Iodine: A Review, <i>J. Clin. Path.</i> , 24:187, 1971
Suntan Lotions	Martin, E.W., Hazards of Medication, Lippincott, Philadelphia, 1971.

3. *Hospital—Radio-opaque Contrast Media and Antiseptic Solutions*

As you undoubtedly know, most contrast media contain iodine (Table 1). And the effects of these media on the PBI usually lasts from months to years. Since the hospital use of iodine-containing contrast media is doubling every five years, this source of PBI contamination is likely to increase. So will the use of iodine-containing antiseptic solutions. As physicians operate more, insert more catheters and tubes, and use more instruments in more body crevices and crannies, more antiseptic solutions will be needed.

Iodipamide (Cholografin®)	4 months	Propylidone (Dionosil®)	up to 5 months
Iodopyracet (Diodrast®)	2 weeks	Acetrizate (Urokon®)	1 month
Diatrizoate (Hypaque®)	1 week	Iophenoxic acid (Teridax®)	many years
Iodized oil (Lipiodol®)	over 5 years	Iodoaliphonic acid (Priodax®)	3 to 4 months
Iophendylate (Pantopaque®)	6 months	Bunamiodyl (Orabilex®)	1 to 2 months
Iopanoic acid (Telepaque®)	5 months	Iodipamide (Biligradin®)	1 month

Table 1—Some Common Contrast Media That Contaminate the PBI. Duration of Contamination is Listed.

4. *Others and More.*

Finally, for completeness, on the next two pages are more sources of iodine contamination. I have unearthed these sources by digging through the literature.

In conclusion, because of widespread and insidious iodine contamination, the PBI will soon become an obsolete test.

Name	Comment	Reference	Name	Comment	Reference
Adipiodone	Contains iodine	1	Iodipamide	Lasts 3-4 months	9
Albumin, Serum	Some albumin preparations are iodinated	2	Cholografin, iodipamide, Meglumine, Sodium Iodipamide, Biligrafin, Radio-selectran		
Antiseptics	If they contain iodine and are used to clean skin	3	Iodoalphonic Acid	Lasts 2-12 months	10
Ethanol, isopropanol			Priodax		
Hydrochlorites, Iodine Compounds, Mercury Compounds, Silver Compounds			Iodocasein	Organic iodine contamination	5
Barium Salts	Occasionally contaminated with organic iodine	3	Iodochlorhydroxyquin, Iodochlorhydroxyquinoline, Clioquinol, Vioform	Contains iodine, effect lasts 2-3 months	11
Barium Sulfate, Erythrotrast			Iodoform	Contains iodine	1
Benziodazone	Contains 36% iodine	4	Iodopyracet	Contains iodine, effect last two weeks	12
Cardivix			Diodrast, Pylumbrine, Pyelobrine, Diodone, Periodil, Pyelosil, Urograf, Vasidone		
Bismuth Salts	Many contain iodine	4	Iodothiouracil	Contains organic iodine, effects lasts 1-4 months	2
Bromides	May be contaminated with iodine	5	5-Iodothiouracil, Itrumul, Iorothiouracil		
Neurosine, Bromide Salts			Iopanoic Acid	Contains organic iodine, effect lasts 1-4 months	9
Bromfulfalein (BSP)	Organic iodide contaminates some solutions	6	Telepaque, Chola-dine, Cistocel, Colepax, Felombrine, Iodopamoic Acid, Teletrast		
Sulfobromophthalein			Iophenoxic Acid	Contains iodide, effect lasts up to 30 years	8
Chinifon	Contains 27.5% iodine	4	Teridax, Trilobrine, Triloshade		
Quinoxyl, Yatren			Iophendylate	Contains iodine, effect lasts up to 5 years	8
Clioquinol	Iodine contamination in some preparations	1	Pantopaque	Contains iodine	1
Chiniform, Chloriodohydroxyquinole, Enteroquinole, Entrine, Enteroseptal, Entero-vioform			Iopydone	Contains iodine	8
Cough Medications	Some contain iodines	5	Iloquine	Contains iodine	1
Dandruff Medications	Some contain iodine	5	Iothalmate	Contains iodine	1
Iloquin, Selenium Sulfide, Cadmium Sulfide			Iothalmate Meglumide Conray, Angio-Conray, Conray-400, Sodium Iothalmate, Iothal-mic Acid		
Decamethonium	Contains 49.5% iodine	5	Iodate	Contains organic iodine	10
Decamethonium iodide, Syecurine, Eulissin			Iodate Calcium, Iodate Sodium, Orografin, Solu-bilopten		
Dextrothyroxine	Contains 65% iodine. May increase PBI to 10-25 meg %. Patients should be followed with T-4	4	Isopropamide	Contains iodine	4
Sodium dextrothyroxine, Dethyrene, Choloxin			Isopropamide Iodide, Tyrimide, Priamide, Darbid, Ornade, Tuss-Ornade		
Diodocaffeine	Contains 66.5% iodine	4	Lipiodal	Contains iodine, effect lasts 1-5 years	9
Diiodocaffeine hydroiodine, Iodocaffeine, Caffedrine			Iodizedoil, Visciodal	Contains iodine and iodide, effect lasts three weeks	9
Diodo hydroxyquin	Contains 65% iodine, effect lasts few weeks		Lugol's Iodine		
Diodoquin, Moebiquin, Yodoxin, Floraquin			Meprobamate	Contains iodine	2
Diodoquinoline	Contains 67% iodine	4	Equanil, Miltown, Arcoban, Mepro-mon CMC, Vioba-mate		
Amoebindoy, Amoequin			Methiodal	Contains iodine, effect lasts 1-2 weeks	9
Diprotazoate	Contains iodine	9	Methiodal Sodium, Skiodam, Retro-paque		
Sodium, Diprotazoate, Miokin			Metracal	Probably due to Iodo-casein content. Lasts 30 days	13
Dimethyltubocuran	Contains 35% iodine	4	Mouth Washes	Some contain iodine	5
Dithiazine	Contains 24.5% iodine	4	Neo-Lopax	Contains iodine, effect lasts 1-2 weeks	8
Dithiazine iodine, Delvex, Partel, Telmid, Anelmid			Penethamate	If given as hydroiodine salt	1
Ethiodal	Contains iodine	7	Penethamate Hydroiodine, Cerespan, Pavabid, Vasopan, Blupau		
Ethiodized oil			Peraphenazine	May contain iodinated contaminants	14
Floraquine	Contains iodine, effect lasts 2-4 weeks	8	Trilafon	Contains iodine	1
Gallamine	Organic iodine contamination	1	Pheniodal		
Gargles	Some contain organic or inorganic iodine	5			
Hippuran	Contain iodine	9			
Sodium Iodohippurate					
Hydroxyquinoline	Present in vaginal suppositories (often iodinated)	2			
Iodocyanine green	Organic iodine contamination	5			
Cardio-green	Effect lasts up to two days	8			
Iodinated Glycerin					

LABORATORY LETTER

Name	Comment	Reference	Name	Comment	Reference
Pink Capsules	Used to encase many drugs. May contain iodine in dye.	5	Tetraiodofluoresce	Red dye used to color many	4
Potassium Iodide	Small doses don't elevate out of normal range, but large ones do.	3	Tetridaz-B	Iodine contamination	5
Mudrane, Pima			Toothpaste	Many contain enough iodine to elevate 1-2 meg%	3
Synate-Mithiokin			Vitamin A & Vitamin D	When given in Cod Liver Oil	16
Propyl iodane	Contains iodine; effect lasts 1-5 months	2	Vitamin Preparations	Iodine contamination	5
Dionsil					
Quinine Iodobis	Contains 57% iodine	4			
Quinine Iodo-histhimate, Bio-iodichinal, Bismo-salvan					
Red-dyed drugs as foods	Presence of Erythrocrine Dye	15			
Suntan oil	Many preparations contain iodine	16

Meetings

OB-Gyn Symposium

On Friday, November 30, 1973, in Minneapolis, Minnesota, the Sixth Annual North Memorial Hospital OB-Gyn Symposium will be held. Selected speakers will discuss current topics of interest in our field. The Symposium will be followed the next day by the annual meeting of the Minnesota State Obstetrics and Gynecological Society. Inquiries should be directed to Alec Janes, MD, Program Chairman, 601 Oakdale Medical Center, Mpls. (55422).

University of Iowa

The fourth Annual Meeting on *Antibiotics and Infection* will be held at the University of Iowa on Thursday, Friday, and Saturday, October 11th, 12th, and 13th. As well as 30 speakers from the University of Iowa Faculty, there will be six guest speakers: Dr. Saul Krugman of New York University; Dr. Gerald L. Mandell of University of Virginia Medical School; Dr. Sergio Rabinovich of the University of Southern Illinois; Dr. Jack S. Remington of Stanford University School of Medicine; Dr. John A. Washington II of the Mayo Clinic Medical School, and Dr. Arthur C. White of Indiana University School of Medicine. Inquiries should be made to Dr. Ian M. Smith, Department of Internal Medicine, University Hospitals, Iowa City, Iowa 52242.

WANTED—One or two F.P. or G.P. for practice in Pine Island, Minnesota. New two-man medical building. Available immediately. Choice of solo or associate practice. Contact: Gerald Regan or James Bale, Tel: 507-356-4529 and 507-356-8343.

INTERESTING AND CHALLENGING POSITION AVAILABLE for an energetic family physician. Clinic with five family physicians, one surgeon and one internist, with a smoothly functioning call system, in a rural community close to the Metropolitan area. Please contact B. A. Orr, M.D., Faribault Clinic, 924 N.E. First Street, Faribault, Minn. 55021 or phone 1-507-334-3921.

MEDICAL DIRECTOR—\$35,000 + BONUS—**CLIENT PAYS OUR FEE**—Major manufacturer seeks G.P. as Medical Director to run complete facility for three plant operation. Will head up main dispensary + three branches, supervise nine nurses, two industrial hygienists and one lab technician. Will be responsible for O.S.H.A. compliance and will supervise all medical exams. Wouldn't you like the luxury of regular 8-5 hours? Call C. Feste collect at 612-544-8601. Employment Counselors.

FULL-TIME FACULTY member needed for special outreach teaching program for senior medical students. This is directly connected with the U of Minnesota Medical School and is an academic appointment. Family Physician preferred. Box 214, Mayo Memorial Bldg., University of Minnesota, Minneapolis, MN 55455.

FOR SALE OR RENT, immediately available, clinic building near downtown Minneapolis hospital, suitable for one to three physicians, completely equipped, about 9 rooms, ample parking. Write MINNESOTA MEDICINE-495, 375, Jackson St., St. Paul 55101.

DO YOU WANT AN INVESTMENT IN THE FUTURE? This home was built for the doctor of the community. To replace this home the cost would be three times the price that is quoted on this home. Some lucky person can purchase this home at thousands of dollars under cost. Will you be the one? It is located in a small town within driving distance of the loop of Minneapolis. The home has everything! No cost or quality of construction was spared in its design and construction when it was built in 1968. Even the cost was many times greater than the purchase price. I can't tell you enough about the home itself. 2354 sq. ft. on main floor and the same square footage finished in the lower level. Central air, inter com, all the appliances in the kitchen including the refrigerator, freezer combination. Laundry room, family room, plus library, sun room, huge living room & dining room, 2½ baths, three bedrooms are on main floor. The fourth bedroom, another bath, billiard room, amusement room, walk in cedar closet and numerous other rooms on the lower level. Even a panelled and heated oversize double garage. The woods used in this home are outstanding. Priced at an unbelievable low price with excellent financing available. Do call now and not miss this opportunity of a lifetime. Eivera Knutson Gri, 890-7875, Edina Realty, 890-4540.

NOVEMBER 1973

Everybody experiences psychic tension.

Most people can handle this tension.

Some people develop excessive psychic tension and need your counselin,

and a few may need counseling
and the psychotropic action of Valium® (diazepam).

Before deciding to make Valium (diazepam) part of your treatment plan, check on whether or not the patient is presently taking drugs and, if so, what his response has been. Along with the medical and social history, this information can help you determine initial dosage, the possibility of side effects and the ultimate prospects of success or failure.

While Valium can be a most helpful adjunct to your counseling, it should be prescribed only as long as excessive psychic tension persists and should be discontinued when you decide it has accomplished its therapeutic task. In general, when dosage guidelines are followed, Valium is well tolerated (see Dosage). For convenience it is available in 2-mg, 5-mg and 10-mg tablets.

Drowsiness, fatigue and ataxia have been the most commonly reported side effects.

Until response is determined, patients receiving Valium should be cautioned against engaging in hazardous occupations requiring complete mental alertness, such as driving or operating machinery.

Before prescribing, please consult complete product information, a summary of which follows:

Indications: Tension and anxiety states; somatic complaints which are concomitants of emotional factors; psychoneurotic states manifested by tension, anxiety, apprehension, fatigue, depressive symptoms or agitation; symptomatic relief of acute agitation, tremor, delirium tremens and hallucinosis due to acute alcohol withdrawal; adjunctively in skeletal muscle spasm due to reflex spasm to local pathology, spasticity caused by upper motor neuron disorders, athetosis, stiff-man syndrome, convulsive disorders (not for sole therapy).

Contraindicated: Known hypersensitivity to the drug. Children under 6 months of age. Acute narrow angle glaucoma; may be used in patients with open angle glaucoma who are receiving appropriate therapy.

Warnings: Not of value in psychotic patients. Caution against hazardous occupations requiring complete mental alertness. When used adjunctively in convulsive disorders, possibility of increase in frequency and/or severity of grand mal seizures may require increased dosage of standard anticonvulsant medication; abrupt withdrawal may be associated with temporary increase in frequency and/or severity of seizures. Advise against simultaneous ingestion of alcohol and other CNS depressants. Withdrawal symptoms (similar to those with barbiturates and alcohol) have occurred following abrupt discontinuance (convulsions, tremor, abdominal and muscle cramps, vomiting and sweating). Keep addiction-prone individuals under careful surveillance because of their predisposition to habituation and dependence. In pregnancy, lactation or women of childbearing age, weigh potential benefit against possible hazard.

Precautions: If combined with other psychotropics or anticonvulsants, consider carefully pharmacology of agents employed; drugs such as phenothiazines, narcotics, barbiturates, MAO inhibitors and other antidepressants may potentiate its action. Usual precautions indicated in patients severely depressed, or with latent depression, or with suicidal tendencies. Observe usual precautions in impaired renal or hepatic function. Limit dosage to smallest effective amount in elderly and debilitated to preclude ataxia or oversedation.

Side Effects: Drowsiness, confusion, diplopia, hypotension, changes in libido, nausea, fatigue, depression, dysarthria, jaundice, skin rash, ataxia, constipation, headache, incontinence, changes in salivation, slurred speech, tremor, vertigo, urinary retention, blurred vision. Paradoxical reactions such as acute hyperexcited states, anxiety, hallucinations, increased muscle spasticity, insomnia, rage, sleep disturbances, stimulation have been reported; should these occur, discontinue drug. Isolated reports of neutropenia, jaundice; periodic blood counts and liver function tests advisable during long-term therapy.

Dosage: Individualize for maximum beneficial effect.

Adults: Tension, anxiety and psychoneurotic states, 2 to 10 mg b.i.d. to q.i.d.; alcoholism, 10 mg t.i.d. or q.i.d. in first 24 hours, then 5 mg t.i.d. or q.i.d. as needed; adjunctively in skeletal muscle spasm, 2 to 10 mg t.i.d. or q.i.d.; adjunctively in convulsive disorders, 2 to 10 mg b.i.d. to q.i.d. *Geriatric or debilitated patients:* 2 to 2½ mg, 1 or 2 times daily initially, increasing as needed and tolerated. (See Precautions.) *Children:* 1 to 2½ mg t.i.d. or q.i.d. initially, increasing as needed and tolerated (not for use under 6 months).

Supplied: Valium® (diazepam) Tablets, 2 mg, 5 mg and 10 mg; bottles of 100 and 500. All strengths also available in Tel-E-Dose® packages of 1000.

acute arthritic inflammation...heat that freezes

In acute rheumatoid arthritis consider Tandearil. The anti-inflammatory action of Tandearil quickly helps reduce heat, pain, swelling, and stiffness. Results are usually seen in 3 or 4 days. Try it for a week when the symptoms defy aspirin control.

Remember that Tandearil is not a simple analgesic. It should not be used in patients responding to routine therapy. Before using, please read the prescribing information. It's summarized below.

Tandearil® helps take the heat off phenylbutazone NF Geigy

tablets of 100 mg.

Important Note: This drug is not a simple analgesic. Do not administer casually. Carefully evaluate patients before starting treatment and keep them under close supervision. Obtain a detailed history, and complete physical and laboratory examination (complete hemogram, urinalysis, etc.) before prescribing and at frequent intervals thereafter. Carefully select patients, avoiding those responsive to routine measures, contraindicated patients, and those who cannot be observed frequently. Warn patients not to exceed recommended dosage. Short-term relief of severe symptoms with the smallest possible dosage is the goal of therapy. Dosage should be taken with meals and a full glass of milk. Patients should discontinue the drug and report immediately any signs of: fever, sore throat, oral lesions (symptoms of blood dyscrasia); dyspepsia, epigastric pain, symptoms of anemia, black or tarry stools or other evidence of intestinal ulceration or hemorrhage, skin reactions, significant weight gain or edema. A one-week trial period is adequate. Discontinue in the absence of a favorable response. Restrict treatment periods to one week in patients over sixty.

Indications: Acute gouty arthritis, rheumatoid arthritis, rheumatoid spondylitis.

Contraindications: Children 14 years or less; multiple patients; history or symptoms of G.I. inflammation or ulceration including severe, current or persistent dyspepsia; history or presence of drug allergy; blood dyscrasias; renal, hepatic or cardiac dysfunction; hyperkalemia; thyroid disease; systemic edema; stomatitis and salivary gland enlargement due to the drug; polymyalgia rheumatica and temporal arteritis; patients receiving other potent chemotherapeutic agents, or long-term anti-ulcerant therapy.

Warnings: Age, weight, dosage, duration of therapy, existence of concomitant diseases, and concurrent potent chemotherapy affect incidence of toxic reactions. Carefully instruct and observe the individual patient, especially the aging (forty years and over) who have increased susceptibility to the toxicity of the drug. Use lowest effective dosage. Weigh potentially unpredictable benefits against po-

tential risk of severe, even fatal, reactions. The disease condition itself is unaltered by the drug. Use with caution in first trimester of pregnancy and in nursing mothers. Drug may appear in cord blood and breast milk. Serious, even fatal, blood dyscrasias, including aplastic anemia, may occur suddenly despite regular hemograms, and may become manifest days or weeks after cessation of drug. Any significant change in total white count, relative decrease in granulocytes, appearance of immature forms, or fall in hematocrit should signal immediate cessation of therapy and complete hematologic investigation. Unexplained bleeding involving CNS, adrenals, and G.I. tract has occurred. The drug may potentiate action of insulin, sulfonamides, and sulfonamide-type agents. Carefully observe patients taking these agents. Nontoxic and toxic goiters and myxedema have been reported (the drug reduces iodine uptake by the thyroid). Blurred vision can be a significant toxic symptom worthy of a complete ophthalmological examination. Swelling of ankles or face in patients under sixty may be prevented by reducing dosage. If edema occurs in patients over sixty, discontinue drug.

Precautions: The following should be accomplished at regular intervals: Careful detailed history for disease being treated and detection of earliest signs of adverse reactions; complete physical examination including check of patient's weight; complete weekly (especially for the aging) or an every two week blood check; pertinent laboratory studies. Caution patients about participating in activity requiring alertness and coordination, as driving a car, etc. Cases of leukemia have been reported in patients with a history of short- and long-term therapy. The majority of these patients were over forty. Remember that arthritic-type pains can be the presenting symptom of leukemia.

Adverse Reactions: This is a potent drug; its misuse can lead to serious results. Review detailed information before beginning therapy. Ulcerative esophagitis, acute and reactivated gastric and duodenal ulcer with perforation and hemorrhage, ulceration and perforation of large bowel, occult G.I. bleeding with anemia,

gastritis, epigastric pain, hematemesis, dyspepsia, nausea, vomiting and diarrhea, abdominal distention, agranulocytosis, aplastic anemia, hemolytic anemia, anemia due to blood loss including occult G.I. bleeding, thrombocytopenia, pancytopenia, leukemia, leukopenia, bone marrow depression, sodium and chloride retention, water retention and edema, plasma dilution, respiratory alkalosis, metabolic acidosis, fatal and nonfatal hepatitis (cholestasis may or may not be prominent), petechiae, purpura without thrombocytopenia, toxic pruritus, erythema nodosum, erythema multiforme, Stevens-Johnson syndrome, Lyell's syndrome (toxic necrotizing epidermolysis), exfoliative dermatitis, serum sickness, hypersensitivity angitis (polyarteritis), anaphylactic shock, urticaria, arthralgia, fever, rashes (all allergic reactions require prompt and permanent withdrawal of the drug), proteinuria, hematuria, oliguria, anuria, renal failure with azotemia, glomerulonephritis, acute tubular necrosis, nephrotic syndrome, bilateral renal cortical necrosis, renal stones, ureteral obstruction with uric acid crystals due to uricosuric action of drug, impaired renal function, cardiac decompensation, hypertension, pericarditis, diffuse interstitial myocarditis with muscle necrosis, perivascular granulomata, aggravation of temporal arteritis in patients with polymyalgia rheumatica, optic neuritis, blurred vision, retinal hemorrhage, toxic amblyopia, retinal detachment, hearing loss, hyperglycemia, thyroid hyperplasia, toxic goiter, association of hyperthyroidism and hypothyroidism (causal relationship not established), agitation, confusional states, lethargy; CNS reactions associated with overdosage, including convulsions, euphoria, psychosis, depression, headaches, hallucinations, giddiness, vertigo, coma, hyperventilation, insomnia; ulcerative stomatitis, salivary gland enlargement. (B)98-146-800-F (10/71)

For complete details, including dosage, please see full prescribing information.

More than sleep

your choice of sleep medication
is wisely based on more than
sleep-inducing potential

sleep with relative safety

Chronic tolerance studies have confirmed the relative safety of Dalmane (flurazepam HCl); no depression of cardiac or respiratory function was noted in patients administered recommended or high doses for as long as 90 consecutive nights.

In most instances when adverse reactions were reported, they were mild, infrequent and self-limiting, requiring discontinuance of therapy. Morning "hang-over" with Dalmane has been relatively infrequent. Drowsiness, lightheadedness and the like have been the side effects noted most frequently, particularly in the elderly and debilitated. (An initial dose of Dalmane 15 mg should be prescribed for these patients.)

sleep for 7 to 8 hours
without need to
repeat dosage

No sleep research laboratory as Dalmane. Insomnia given one 30-mg capsule of Dalmane at bedtime, on average: fell asleep within 17 minutes, had few time awakenings, spent less time awake after sleep onset, and slept for 7 to 8 hours with no need to repeat dosage during the night.

ep with
sistency

Dalmane (flurazepam HCl) is a distinctive sleep medication—a benzodiazepine specifically indicated for insomnia. It is not a barbiturate or methaqualone, nor is it related chemically to any other hypnotic.

When your evaluation of insomnia indicates the need for a sleep medication, consider Dalmane—a single entity nonnarcotic, non-habit-forming agent proved effective and relatively safe for relief of insomnia.

Dalmane has been shown to be consistently effective even during consecutive nights of administration, with no need to increase dosage.

DALMANE[®]
(flurazepam HCl)

**When restful sleep
is indicated**

One 30-mg capsule h.s. —usual adult dosage
(15 mg may suffice in some patients)

One 15-mg capsule h.s. —initial dosage for elderly or debilitated patients.

Before prescribing Dalmane (flurazepam HCl), please consult Complete Product Information, a summary of which follows:

Indications: Effective in all types of insomnia characterized by difficulty in falling asleep, frequent nocturnal awakenings and/or early morning awakening in patients with recurring insomnia or poor sleeping habits, and in acute or chronic medical situations requiring restful sleep. Since insomnia is often transient and intermittent, prolonged administration is generally not necessary or recommended.

Contraindications: Known hypersensitivity to flurazepam HCl.

Warnings: Caution patients about possible combined effects with alcohol and other CNS depressants. Caution against hazardous occupations requiring complete mental alertness (e.g., operating machinery, driving). Use in women who are or may become pregnant only when potential benefits have been weighed against possible hazards. Not recommended for use in persons under 15 years of age. Though physical and psychological dependence have not been reported on recommended doses, use caution in administering to addiction-prone individuals or those who might increase dosage.

Precautions: In elderly and debilitated, initial dosage should be limited to 15 mg to preclude oversedation, dizziness and/or ataxia. If combined with other drugs having hypnotic or CNS-depressant effects, consider potential additive effects. Employ usual precautions in patients who are severely depressed, or with latent depression or suicidal tendencies. Periodic blood counts and liver and kidney function tests are advised during repeated therapy. Observe usual precautions in presence of impaired renal or hepatic function.

Adverse Reactions: Dizziness, drowsiness, lightheadedness, staggering, ataxia and falling have occurred, particularly in elderly or debilitated patients. Severe sedation, lethargy, disorientation and coma, probably indicative of drug intolerance or overdose, have been reported. Also reported were headache, heartburn, upset stomach, nausea, vomiting, diarrhea, constipation, GI pain, nervousness, talkativeness, apprehension, irritability, weakness, palpitations, chest pains, body and joint pains and GU complaints. There have also been rare occurrences of sweating, flushes, difficulty in focusing, blurred vision, burning eyes, faintness, hypotension, shortness of breath, pruritus, skin rash, dry mouth, bitter taste, excessive salivation, anorexia, euphoria, depression, slurred speech, confusion, restlessness, hallucinations, and elevated SGOT, SGPT, total and direct bilirubins and alkaline phosphatase. Paradoxical reactions, e.g., excitement, stimulation and hyperactivity, have also been reported in rare instances.

Dosage: Individualize for maximum beneficial effect. *Adults:* 30 mg usual dosage; 15 mg may suffice in some patients. *Elderly or debilitated patients:* 15 mg initially until response is determined.

Supplied: Capsules containing 15 mg or 30 mg flurazepam HCl.

ROCHE LABORATORIES

Nutley, New Jersey 07110

It's time for action to defend the laws and regulations that protect your patients against drug substitution.

These professional and trade organizations are united in supporting antisubstitution statutes and regulations.

The American Academy of Dermatology

The Board of Directors of the American Academy of Family Physicians

The Executive Board of the American Academy of Neurology

The Committee on Drugs of the American Academy of Pediatrics

The American College of Allergists

The Executive Committee of the American College of Obstetricians and Gynecologists

The Board of Regents of the American College of Physicians

The Board of Trustees of the American Dental Association

The Board of Trustees of the American Medical Association

The American Psychiatric Association

The Executive Committee of the National Association of Retail Druggists

The Board of Directors of the Pharmaceutical Manufacturers Association

The National Wholesale Druggists' Association

Statement on Antisubstitution Laws and Regulations

The purpose of this statement is to affirm the support of the participating organizations for the laws, regulations and professional traditions which prohibit the unauthorized substitution of drug products.

Traditionally, physicians, dentists and pharmacists have worked cooperatively to serve the best interests of patients. Productive cooperation has been achieved through mutual respect as well as a common concern for the ideals of public service. This mutual respect has been evidenced, in part, by joint support over the years for the adoption and enforcement of laws and regulations which prohibit unauthorized substitution and encourage joint decision and selection of the best drug supply of drug products. Basic principles of medical, dental and pharmacy practice are thus maintained and preserved in the interest of patient welfare.

The antisubstitution laws have obstructed enhancement of the professional status of pharmacy any more than they have in and of themselves guaranteed absolute protection from unsafe drugs, or freed physicians, dentists and pharmacists from their responsibilities to patients. In fact, on the practical matter, however, such laws and regulations encourage interprofessional communications regarding drug product selection and assure each profession the opportunity to use fully its expertise in drug selection to the advantage of patients.

Physicians and dentists should be encouraged to increase the frequency and regularity of their contacts with pharmacists in selection of quality drug products, recognizing that

economies to patients can be improved through such communication, taking into account the patients' needs. The pharmacist's knowledge of the chemical characteristics of drugs, their mode of action, toxic properties and other characteristics that assist in making drug selection decisions should be utilized to the fullest extent practicable by physicians and dentists in serving their patients.

Since drug product selection entails knowledge derived from clinical experience, the physician's and dentist's roles in product selection remain primary and do not permit delegation of decisions requiring medical and dental judgments. A broader role in therapy will evolve for pharmacists as improved understanding and cooperation among the professions continue to grow.

There has been no evidence that there are convincing reasons to modify or repeal existing laws and regulations prohibiting the unauthorized substitution of another drug product for the one specified by a prescriber. It is our belief that such laws and regulations merit the joint support of the medical, dental and pharmaceutical professions and the pharmaceutical industry.

Add your opinion to the weight of other professionals and send it to your state assemblyman or legislator.

ROCHE announces new

BACTRIMTM

Each tablet contains 80 mg trimethoprim and 400 mg sulfamethoxazole.

a new type of antibacterial for a two-pronged attack against chronic urinary tract infections due to susceptible organisms

Bactrim is highly effective in the treatment of these infections—primarily pyelonephritis, pyelitis and cystitis—when due to susceptible organisms. This efficacy is related to the unique mode of action against bacteria (see illustration), an action that, in effect, makes Bactrim a new type of antibacterial.

Bactrim interrupts the life cycle of susceptible bacteria

Unique mode of action interrupts the life cycle at two important points, thereby impeding the production of nucleic acids and proteins essential to these bacteria. These consecutive interruptions occur because sulfamethoxazole and trimethoprim resemble naturally existing substrates. By competitive replacement of these substrates, they inhibit further synthesis.

new **BACTRIM**TM

Each tablet contains 80 mg trimethoprim and 400 mg sulfamethoxazole.

for chronic urinary tract infections

Before prescribing, please see complete product information on last page of advertisement.

Excellent clinical response in chronic urinary tract infections even with obstructive complications

A multiclinic, double-blind study* of response to a ten-day course of therapy in 471[†] patients with chronic urinary tract infections demonstrated the superiority of Bactrim. On the 10th day after initiation of therapy, 91.7% (of 168 patients) showed significant bacteriological response to Bactrim, compared with 81.2% (of 144 patients) to trimethoprim and 64.5% (of 155 patients) to sulfamethoxazole. More than half of these patients had obstructive complications.

Excellent response maintained

Bactrim proved equally impressive in maintaining this bacteriological response. In the above study, after a ten-day course of therapy with Bactrim, 68.4% of patients with chronic urinary tract infections *maintained* response for up to 42 consecutive days, compared with 59.7% with trimethoprim and 44.4% with sulfamethoxazole. These results are particularly noteworthy considering the number of patients with obstructive complications—cases regarded as being notoriously difficult to treat.

Prescribing considerations

Clinical Limitations: Currently, the increasing frequency of resistant organisms is a limitation of usefulness of all antibacterial agents, especially in the treatment of chronic and recurrent urinary tract infections. Not recommended for children under twelve.

Contraindications: Hypersensitivity to trimethoprim or sulfonamides. Pregnancy and during the nursing period.

Warnings and Precautions: Both sulfamethoxazole and trimethoprim have been reported to interfere with hematopoiesis. Complete blood counts should be done frequently. If a significant reduction in the count of any formed blood element is noted, Bactrim should be discontinued. Bactrim should be given with caution to patients with impaired renal or hepatic function, possible folate deficiency, severe allergy or bronchial asthma. Maintain adequate fluid intake. Urinalyses with careful microscopic examination and renal function tests should be performed during therapy, particularly for those patients with impaired renal function.

Adverse Effects: Among the most common side effects are nausea, vomiting, rash, leukopenia and elevations in SGOT and creatinine.

Usual adult dosage: two tablets every twelve hours for 10 to 14 days; no loading dose required.

Before prescribing, please consult complete product information on facing page.

Complete Product Information:

Description: Bactrim is a synthetic antibacterial combination product, available in scored light-green tablets, each containing 80 mg trimethoprim and 400 mg sulfamethoxazole.

Trimethoprim is 2,4-diamino-5-(3,4,5-trimethoxybenzyl) pyrimidine. It is a white to light-yellow, odorless, bitter compound with a molecular weight of 290.3.

Sulfamethoxazole is N¹-(5-methyl-3-isoxazolyl)sulfanilamide. It is almost white in color, odorless, tasteless compound with a molecular weight of 253.28.

Actions: Microbiology: Sulfamethoxazole inhibits bacterial synthesis of dihydrofolic acid by competing with para-aminobenzoic acid. Trimethoprim blocks the production of tetrahydrofolic acid from dihydrofolic acid by binding to and reversibly inhibiting the required enzyme, dihydrofolate reductase. Thus, Bactrim blocks two consecutive steps in the biosynthesis of nucleic acids and proteins essential to many bacteria.

In vitro studies have shown that bacterial resistance develops more slowly with Bactrim than with trimethoprim or sulfamethoxazole alone.

In vitro serial dilution tests have shown that the spectrum of antibacterial activity of Bactrim includes the common urinary tract organisms with the exception of *Pseudomonas aeruginosa*. The following organisms are usually susceptible: *Escherichia coli*, *Klebsiella-Enterobacter*, *Proteus mirabilis* and indole-positive proteus species.

Representative Minimum Inhibitory Concentration Values for Bactrim-Susceptible Organisms (MIC—mcg/ml)

Organism	Trimethoprim alone	Sulfamethoxazole alone	TMP/SMX (1:20)	
			TMP	SMX
<i>Escherichia coli</i>	0.05—1.5	1.0 —245	0.05—0.5	0.95— 9.5
<i>Proteus</i> spp.	0.5 —5.0	7.35 —300	0.05—1.5	0.95—28.5
<i>Indole positive proteus</i>	0.5 —1.5	7.35 — 30	0.05—0.15	0.95— 2.85
<i>Klebsiella-Enterobacter</i>	0.15—5.0	0.735—245	0.05—1.5	0.95—28.5

Human Pharmacology: Bactrim is rapidly absorbed following oral administration. The blood levels of trimethoprim and sulfamethoxazole are similar to those achieved when each component is given alone. Peak blood levels for the individual components occur one to four hours after oral administration. The half-lives of sulfamethoxazole and trimethoprim, 10 and 16 hours respectively, are relatively the same regardless of whether these compounds are administered as individual components or as Bactrim. Detectable amounts of trimethoprim and sulfamethoxazole are present in the blood 24 hours after drug administration. Free sulfamethoxazole and trimethoprim blood levels are proportionately dose-dependent. Following repeated administration, the steady-state ratio of trimethoprim to sulfamethoxazole levels in the blood is about 1:20.

Sulfamethoxazole exists in the blood as free, conjugated and protein-bound forms; trimethoprim is present as free, protein-bound and metabolized forms. The free forms are considered to be the therapeutically active forms. Approximately 44 percent of trimethoprim and 70 percent of sulfamethoxazole are protein-bound in the blood. The presence of 10 mg percent sulfamethoxazole in plasma increases the protein binding of trimethoprim to an insignificant degree; trimethoprim does not influence the protein binding of sulfamethoxazole.

Excretion of Bactrim is chiefly by the kidneys through both glomerular filtration and tubular secretion. Urine concentrations of both sulfamethoxazole and trimethoprim are considerably higher than the concentrations in the blood. When administered together as Bactrim, neither sulfamethoxazole nor trimethoprim affects the urinary excretion pattern of the other.

Indications: Chronic urinary tract infections (primarily pyelonephritis, pyelitis and cystitis) due to susceptible organisms (usually *E. coli*, *Klebsiella-Enterobacter*, *Proteus mirabilis*, and, less frequently, indole-positive proteus species).

Important note: Currently, the increasing frequency of resistant organisms is a limitation of the usefulness of all antibacterial agents, especially in the treatment of chronic and recurrent urinary tract infections.

Contraindications: Hypersensitivity to trimethoprim or sulfonamides. Pregnancy and during the nursing period (See Reproduction Studies).

Warnings: Deaths associated with the administration of sulfonamides have been reported from hypersensitivity reactions, agranulocytosis, aplastic anemia and other blood dyscrasias. Experience with trimethoprim alone is much more limited, but it has been reported to interfere with hematopoiesis in occasional patients. In elderly patients concurrently receiving certain diuretics, primarily thiazides, an increased incidence of thrombopenia with purpura has been reported.

The presence of clinical signs such as sore throat, fever, pallor, purpura or jaundice may be early indications of serious blood disorders. Complete blood counts should be done frequently in patients receiving Bactrim. If a significant reduction in the count of any formed blood element is noted, Bactrim should be discontinued.

At the present time, there is insufficient clinical information on the use of Bactrim in infants and children under 12 years of age to recommend its use.

Precautions: Bactrim should be given with caution to patients with impaired renal or hepatic function, to those with possible folate deficiency and to those with severe allergy or bronchial asthma. In glucose-6-phosphate dehydrogenase-deficient individuals, hemolysis may occur. This reaction is frequently dose-related. Adequate fluid intake must be maintained in order to prevent crystalluria and stone formation. Urinalyses with careful microscopic examination and renal function tests should be performed during therapy, particularly for those patients with impaired renal function.

Adverse Reactions: For completeness, all major reactions to sulfonamides and to trimethoprim are included below, even though they may not have been reported with Bactrim.

Blood dyscrasias: Agranulocytosis, aplastic anemia, megaloblastic anemia, thrombopenia, leukopenia, hemolytic anemia, purpura, hypoprothrombinemia and methemoglobinemia.

Allergic reactions: Erythema multiforme, Stevens-Johnson syndrome, generalized skin eruptions, epidermal necrolysis, urticaria, serum sickness, pruritus, exfoliative dermatitis, anaphylactoid reactions, periorbital edema, conjunctival and scleral injection, photosensitization, arthralgia and allergic myocarditis.

Gastrointestinal reactions: Glossitis, stomatitis, nausea, emesis, abdominal pains, hepatitis, diarrhea and pancreatitis.

C.N.S. reactions: Headache, peripheral neuritis, mental depression, convulsions, ataxia, hallucinations, tinnitus, vertigo, insomnia, apathy, fatigue, muscle weakness and nervousness.

Miscellaneous reactions: Drug fever, chills, and toxic nephrosis with oliguria and anuria. Periarteritis nodosa and L. E. phenomenon have occurred.

The sulfonamides bear certain chemical similarities to some goitrogens, diuretics (acetazolamide and the thiazides) and oral hypoglycemic agents. Goiter production, diuresis and hypoglycemia have occurred rarely in patients receiving sulfonamides. Cross-sensitivity may exist with these agents. Rats appear to be especially susceptible to the goitrogenic effects of sulfonamides, and long-term administration has produced thyroid malignancies in the species.

Dosage and Administration: Not recommended for use in children under 12 years of age.

The usual adult dosage is two tablets every 12 hours for 10 to 14 days.

For patients with renal impairment:

Creatinine Clearance (ml/min)	Recommended Dosage Regimen
Above 30	Usual standard regimen
15-30	2 tablets every 24 hours
Below 15	Use not recommended

How Supplied: Tablets, containing 80 mg trimethoprim and 400 mg sulfamethoxazole—bottles of 100 and 500; Tel-E-Dose® packages of 1000; Prescription Paks of 40, available singly and in trays of 10. Imprint on tablets: ROCHE 50.

Reproduction Studies: In rats, doses of 533 mg/kg sulfamethoxazole or 200 mg/kg trimethoprim produced teratological effects manifested mainly as cleft palates. The highest dose which did not cause cleft palates in rats was 512 mg/kg sulfamethoxazole or 192 mg/kg trimethoprim when administered separately. In two studies in rats, no teratology was observed when 512 mg/kg of sulfamethoxazole was used in combination with 128 mg/kg of trimethoprim. However, in one study, cleft palates were observed in one litter out of 9 when 355 mg/kg of sulfamethoxazole was used in combination with 88 mg/kg of trimethoprim.

In rabbits, trimethoprim administered by intubation from days 8 to 16 of pregnancy at dosages up to 500 mg/kg resulted in higher incidences of dead and resorbed fetuses, particularly at 500 mg/kg. However, there were no significant drug-related teratological effects.

REUBEN BERMAN, M.D., Editor-in-Chief

President's Letter

Shortening the Hospital Stay

THERE IS LATELY a strange swell of enthusiasm for shortening hospital stay. Many of us remember great surges of the past toward brief hospitalization—the observation that early ambulation of older people resulted in lower morbidity and mortality as well as much earlier return home was an impressive breakthrough. The developments in anesthesia which permitted not only more extensive surgical procedures but resulted in diminution of trauma and better survival had a similar effect. Antibiotics shortened hospital stays of patients with infectious diseases, and in many cases obviated the need for hospitalization at all. The phenothiazines of the 50's sent many psychiatric patients out of hospital and back to families in record short order. These advances had to do with improved patient care, lessened morbidity and lowered mortality.

The new vogue in short hospital stay seems to have little to do with improved care—or relieving pain—or saving lives. Rather clearly it is based on economic considerations. There is much talk of 5th percentile review, 90th percentile review, utilization review, pre-admission authorization. There even was a recent article in a renowned scientific journal which ecstatically described procedures resulting in spectacular shortening of patient stay. The strange and awful thing is that little was mentioned about treatment results, relief of suffering, patient comfort or ultimate outcome.

This new interest in shortening hospital time appears to be mothered by Congress and fathered by no one knows whom. One wonders if the infant is parthenogenic or possibly if the putative father could be the insurance industry. In any case, with paternity in doubt there are many among us who have no hesitation in questioning the legitimacy (or illegitimacy) of this infant.

What if the insurance industry does turn out to be the true father of this lusty sprout? Can

this monetary giant seduce the infant's mother into an indiscretion which will end in impairment of medical care? Is it true that he who pays the fiddler calls the tune? Certainly this industry represents a monstrous accumulation of wealth—some say an undue accumulation. I know of no wealthy doctors save those few who inherited fortunes from an ancestor of unusual resources or the even fewer who married a wealthy girl and settled into a life of affluence. On the other hand, I know of many wealthy insurance companies and insurance executives—and they wield enormous power. One observes on driving into almost any American city, that one can view the skyline and identify with fair assurance the largest and grandest structure as being the headquarters of an insurance company. Even further, one can recount stories of insurance industry arrogance in dealing with municipalities, with politicians, with people and now frighteningly with medical care of our patients.

What must our posture be as physicians? We who are skilled in the care of illness by training, by experience and by mature judgment must continue to be more concerned for the health of our patients than for the financial well-being of an industry or a department of government. The welfare of the sick must be measured in humanitarian rather than fiscal terms. Physicians must be more concerned with relieving and healing and in helping than with shortening a stay for a statistically described condition from 7.8 to 7.6 days.

Carotid-Cavernous Fistula

EDWARD L. SELJESKOG, M.D., Ph.D.*

OF THE MANIFOLD MEDICAL and surgical problems encountered in neurosurgical practice, few lesions have garnered the attention that has been afforded the problem of carotid-cavernous fistula. This interest has mainly related to the profound neurologic impairment frequently present-

ing in these patients, but secondarily it has related to the striking associated signs and symptomatology. Until recently, the general topic of carotid-cavernous fistula was usually discussed under the heading of "Pulsating Exophthalmus," but it should be noted that not all cases of carotid-cavernous fistula demonstrate this classical finding. Through the years, carotid-cavernous fistulae have been known by a number of different titles: aneurysm of the ophthalmic artery (or vein), arterial-venous anastomosis, orbital erectile tumor, pulsating exophthalmus carotid-cavernous aneurysm, and, of course, the most common term, carotid-cavernous fistula (CCF).

History

In 1811, Benjamin Travers, a London surgeon, first described the basic pathophysiology in CCF. He proposed that the symptoms and findings in this entity were related to a fistulous connection between the carotid artery and the cavernous venous sinus. Knowledge of William Hunter's classic description of a typical A-V fistula, of some fifty years earlier, led Travers to this account. In 1808, Travers had assisted Ashley Cooper, another London surgeon, with a carotid ligation for an entirely different problem. He then correctly surmised that

*Department of Neurosurgery, University of Minnesota Medical School, Minneapolis, Minnesota.
See editorial, page 966.

Fig. 1—Cross section of the sella and cavernous sinus demonstrating the intracavernous carotid artery completely surrounded by the septated venous sinus. Note also the relationship of the carotid artery to the III, IV, V, and VI cranial nerves.

Fig. 2—Horizontal section of the skull revealing the major intracranial dural venous sinuses and their communication with the cavernous sinus.

Fig. 3—View of the cavernous sinus illustrating the small intracavernous branches of the carotid artery. These vessels may significantly enlarge and serve as a continued arterial supply to the incompletely occluded CCF.

if the artery leading into a fistula could be ligated, the potential for cure of this abnormality then existed. Management of his case in this fashion then resulted in an apparent cure.

Guthrie, in 1823, carried out an autopsy on a probable case of CCF. Surprisingly, he described what he thought to be an aneurysm of the ophthalmic artery, but after reading the details of the case, one is soon left with the realization that this patient likely had a CCF and that the apparent ophthalmic artery aneurysm was in reality an aneurysmal dilatation of one of the ophthalmic veins. Nevertheless, this led British medical thought to consider the general problem of "Pulsating Exophthalmus" as being related to an aneurysm of either the ophthalmic artery or vein.

The "French School of Medicine" developed a different concept of this problem. Delens, in 1879, described in detail a typical CCF which was related to a ruptured intracavernous carotid artery aneurysm. Additionally, he described a second type of case involving a post-traumatic CCF. In this patient, there was a traumatic disruption of the arterial wall with a secondarily developing carotid artery-cavernous venous sinus fistula. In actuality, this traumatic lesion had been duplicated in the morgue by driving a spike into the orbit thereby demonstrating the potential for development of this arterio-venous connection. Gradually, it became quite universally accepted that this entity was basically a problem of a fistulous connection between the intracavernous carotid artery and the cavernous venous sinus.

Two general causes of CCF are then apparent. First, those cases which are spontaneous in nature and which are thought to be related to rupture of an intracavernous carotid aneurysm. Second are those cases which are traumatic in origin, usually related to a skull fracture, or penetrating cranial injury. In 1966, Hamby¹ in his excellent monograph and presentation of 42 cases, found a nearly equal number (19/23) of the traumatic and spontaneous types. The general literature, however, seems to imply a ratio of about three to one and, as one might anticipate, the traumatic fistula is much more common in the young male, undoubtedly a reflection of the greater exposure of this patient group to injuries and their sequelae.

Spontaneous fistulae are strikingly more common in women especially during pregnancy with a much greater frequency than one would anticipate from a strict statistical appraisal of the problem.

Of Hamby's¹ 16 cases of spontaneous CCF in women, two had onset of their symptoms during pregnancy. Since this type of CCF is thought to be due to rupture of an intracavernous carotid aneurysm, it is possible that vascular changes, hypertensive factors and the straining associated with pregnancy and delivery may predispose this type of aneurysm to rupture during this period of life. An additional factor appears to be a congenital predisposition to the development of intracavernous aneurysms, since several cases of unilateral CCF have been found to have an asymptomatic contralateral intracavernous carotid aneurysm. Intracavernous aneurysms are extremely uncommon; therefore, this degree of bilaterality is much greater than one would statistically anticipate.

In general, traumatic CCF develops following a head injury where there is a basilar skull fracture. The fracture usually traverses the floor of the middle fossa to the parasellar area involving the carotid artery in this region. A number of delayed cases of traumatic CCF have been reported, actually some several weeks following the initial injury. It has been proposed that in this situation there initially develops a traumatic intimal tear, which then subsequently develops an aneurysmal dilatation, ultimately rupturing, creating the fistula. Generally, however, the signs and symptoms of CCF are present quite early following the traumatic episode. Occasional cases of this type of fistula are related to a penetrating injury of the orbital area, as in Delens's early description.

Anatomy

The carotid artery within the cavernous sinus lies in a unique position as it passes from the bony carotid canal into the intracranial cavity. Within the sinus, the artery lies between the two leaves of the dura nearly surrounded completely by venous blood (Figure 1). The carotid artery is obviously predisposed to develop an A-V fistula with any type of disruption of its wall in this location.

The cavernous sinus is one of the major intracranial dural venous sinuses receiving a considerable portion of the superficial venous drainage from the inferior frontal and temporal lobes (Figure 2). Anteriorly, there is communication through the superior orbital fissure with the superior and inferior ophthalmic veins and through them to the extracranial facial venous system. This is the well known avenue by which facial and orbital infec-

ion travel producing a cavernous sinus phlebitis with catastrophic thrombosis.

Within the cavernous sinus several important structures lie in close apposition to the carotid artery (Figure 1). These include the ophthalmic division (V_1) of the trigeminal nerve, as well as the VI cranial (abducens) nerve to the lateral rectus muscle. Both of these structures lie quite laterally, while more medially and superiorly lie the II and IV cranial nerves (oculomotor and trochlear), supplying the remaining extraocular muscles. As a consequence, any type of pathologic process distending and stretching the sinus walls will likely affect these structures. This is particularly true when the nerves are stretched over a mass such as an aneurysm.

The ophthalmic artery is the first intracranial, intradural branch of the carotid artery. This vessel usually arises just as the carotid artery penetrates the dura beneath the optic nerve (Figure 3). However, this vessel many times originates within the cavernous sinus and can thereby serve as an additional source of arterialized blood to the fistula through reversal of its blood flow from its orbital-facial collateral. Minute intracavernous branches may become important in the problem of CCF, in that they may enlarge and serve as a source for continued arterial feeding of an incompletely occluded fistula.²

Signs and Symptoms

Bruit

It is stated that about 80% of the cases of CCF have an audible bruit. This may or may not be audible to the patient. In the 42 cases of Hamby¹, 41 eventually developed a bruit and in 29 it was the initial symptom. The patient may describe the bruit under such terms as: bird-like, squealing, roaring, or humming. Occasionally, the bruit is loud enough to be heard by an observer some several feet distant and may be the most seriously disabling symptom. Many patients soon discover that carotid compression results in a decrease in the intensity of their bruit and again, in Hamby's¹ series, 34/37 tested patients developed a definite alteration or obliteration of the bruit with this maneuver.

Exophthalmus and Pulsations

The development of exophthalmus is generally noted the first day following an injury. However, some cases only develop this problem after sev-

eral weeks as has been previously discussed. As expected, the exophthalmus invariably begins on the side of the fistula with possible later contralateral signs. Basically, the proptosis is secondary to orbital venous hypertension, particularly involving the superior ophthalmic vein and usually producing a downward and outward protrusion of the eye (Figures 4-6). Occasional individuals afflicted with this condition have reported an increase in their exophthalmus with straining or coughing. In Hamby's¹ series, 40/42 patients had evidence of proptosis. In 1950, Sir Geoffrey Jefferson³ described a case of spontaneous CCF that initially developed exophthalmus contralateral to the fistula. In this patient, there was noted a rather large ipsilateral intracavernous aneurysm which likely obstructed the forward venous outflow into the ipsilateral orbit, while allowing the increased venous pressure to be transmitted through the intercavernous sinuses to the contralateral cavernous sinus and orbit.

In Hamby's¹ series of cases, 14/42 patients demonstrated the presence of a pulsating type of exophthalmus. Many times these pulsations were not visible, but palpable only to the finger tip.

Chemosis

This sign is a frequent finding with problems of CCF and includes the basic problem of scleral injection (Figures 7 and 8) as well as edema of the lid and conjunctiva. (Figures 9 and 10). Again this is related to intraorbital venous hypertension. Eyelid edema may be so severe (Figures 11 and 12) that the lids will evert, leading to secondary infection. Occasional cases may also demonstrate epistaxis related to venous congestion of the nasal mucosa.

Visual Failure

Visual failure is also a frequent finding. It is thought that this primarily relates to a depression of retinal blood flow secondary to venous hypertension. Other important factors include papilledema with retinal edema and venous hemorrhage, retinal hemorrhage and detachment, vitreous hemorrhage, glaucoma (secondary to anterior chamber venous hypertension), stretching of the optic nerve (due to exophthalmus), corneal opacities (secondary to neovascularization), and corneal ulceration and edema (secondary to exposure and infection). About 50% of the cases of CCF ultimately develop some degree of visual loss. Usually, one notes, after successful treat-

Fig. 10—Example of the typical chemosis found in CCF.

ment, a primary type of optic atrophy, suggesting that the majority of visual loss is related to retinal ischemia or nerve stretch.

Extraocular Nerve Palsy

Paralysis of one of the extraocular muscles in problems of CCF is a relatively common finding. The VI nerve is the most common single nerve involved, but usually the situation is one of (Figure 13) multiple extraocular muscular (EOM) involvement. In Hamby's¹ series, 24/42 patients had symptoms of diplopia. Exophthalmus rather than direct nerve distortion may also contribute to this problem.

Headache

Headache is also a frequent complaint in CCF. It is thought to be mainly due to intracranial dural venous distention, however, increased intracranial pressure may also play a role.

Other Cranial Nerve Palsies

As one might anticipate from the anatomy of the area (Figures 1 and 3), the trigeminal nerve and most particularly its ophthalmic division (V_1) may be involved in CCF. This is more frequent in the spontaneous type of fistula with an associated aneurysm, where there may be direct stretching of the nerve by the aneurysm and dilated sinus. Of Hamby's¹ cases, 12/42 had evidence of hypesthesia involving V_1 . Other cranial nerves may be involved, such as VII or VIII, but this usually is related to a basilar skull fracture, rather than by involvement with the fistula.

Vascular Changes

Very occasionally, one may note dilatation of facial veins in the area of the CCF. Undoubtedly, this is related to venous hypertension of orbital collateral vessels. On angiography, an increased diameter of the carotid and ophthalmic arteries may be noted, but problems of high output cardiac failure are rarely seen, since the fistula usually becomes locally symptomatic before the problem has any serious hemodynamic significance from the cardiac standpoint.

Cerebral Ischemia

This again is not an unusual problem in CCF, particularly in the elderly. It is felt to be primarily related to the siphoning effect of the fistula, essentially "robbing" the ipsilateral hemisphere of a significant portion of its carotid blood flow (Figure 14). One should bear in mind that in this type of case, symptoms of cerebral ischemia would only be aggravated by an extracranial carotid artery ligation.

Differential Diagnosis

In the uncomplicated case of CCF, the diagnosis is usually obvious, particularly when confronted with the symptom complex of pulsating exophthalmus and an orbital bruit. The suspected diagnosis is then further corroborated when or notes relief of the symptomatology by carotid compression. However, a number of other problems should be considered in the differential diagnosis. These include:

Cavernous Sinus Thrombosis

In this problem, the diagnosis is usually evident with an antecedent history of fever and signs and symptoms of sepsis. Occasionally, these individuals can present with an isolated problem of proptosis, and at times chemosis and EOM paresis. Visual failure may be present to some degree due to the infection and/or associated papilledema. The differentiation really relates to the patient's prior history of infection, but additionally there will be no evidence of pulsation or bruit.

Retro-Orbital Tumor

In general, this type of problem has a rather insidious onset, rather than the abrupt onset that is usually associated with a spontaneous or traumatic CCF. The patients frequently have a superior orbital fissure syndrome, which includes involvement of the III, IV, and VI cranial nerves as well as the V_1 division of the trigeminal nerve. There will usually be no bruit, nor evidence of pulsation so often noted with a CCF.

Orbital Aneurysms

True arterial or venous orbital aneurysms are a rarity in clinical practice. The differentiation from CCF is quite difficult, since basically, the patient does present with a problem of pulsating exophthalmus. Undoubtedly, a number of the early descriptions of orbital aneurysms, were in actuality CCF. These individuals do not have the signs and symptoms of venous engorgement and angiography ultimately defines this type of lesion.

Orbital A-V Malformation

Again this is a rare entity. Undoubtedly, most of the early cases of orbital A-V malformation were related to venous hypertension and a CCF. Again this problem is delineated by angiography which obviously is a necessity to clearly differentiate this unusual problem from a true CCF.

Orbital Encephalocele

This unusual problem is related to a herniation of cerebral tissue through a congenital or post-traumatic defect in the orbital roof. These in-

Individuals obviously become more symptomatic if intracranial pressure is increased for any reason. The exophthalmus in this situation is secondary to the mass of the encephalocele and the pulsatile quality is related to transmitted cerebral pulsations. These patients will not have a bruit and x-rays of the skull will reveal evidence of an orbital roof defect, as well as possible associated findings of increased intracranial pressure. Additionally, the patients rarely have any significant visual loss or extraocular involvement, nor is there any evidence of orbital venous hypertension.

Diagnosis

The diagnosis of a CCF is primarily clinical, taking into account the classical clinical signs, symptoms and history. If necessary, the diagnosis can be corroborated by a carotid compression test and angiography. Angiography may reveal a number of different vascular patterns, but basically, the fistula is revealed by a very prompt and early opacification or leakage of contrast material into the cavernous sinus, as soon as the contrast media reaches the carotid siphon (Figures 15 and 16). Occasionally, in spontaneous cases, an intracavernous aneurysm may be noted, although this is infrequent due to the dense opacification of the sinus region by the contrast material (Figures 17 and 18). The venous drainage from the cavernous sinus may be along a number of different avenues. It may be chiefly forward into the superior ophthalmic vein and orbit (Figure 19 and 20), but at times there is very prompt filling of the sphenoparietal sinus, sylvian vessels and then the superior sagittal sinus (Figure 21). The major venous drainage can also be in a posterior direction into the basilar venous plexus and petrosal sinuses to the region of the jugular bulb (Figures 22 and 23). An additional point of interest relates to the jugular venous oxygen tension, which in CCF is usually elevated. This should not be considered as an essential part of the patient's initial evaluation.

Management

The Untreated Carotid-Cavernous Fistula

A number of possibilities exist for the ultimate destiny of the untreated CCF. These include: (A) Spontaneous closure, (B) Fatal hemorrhage, and (C) Static or slowly progressive signs and symptoms.

Spontaneous Cure In a review of the problem of CCF, Sattler,⁴ in 1920, garnered from the literature some 322 cases of CCF. Eighty-one patients of this group had no treatment and in sixteen there developed an apparent spontaneous cure. Pool⁵ in discussing this review, pointed out that a large number of these patients had a subsequent recurrence of their symptomatology (13/16). Therefore, only 3/81 (3.7%) patients who had no treatment did there develop an apparent spontaneous cure. The mortality in this group of 81 patients was about 10% and 72% of the patients had no improvement in their symptomatology, which at times was incapacitating. Hamby's¹ monograph indicated that 4/42 patients of his group had no specific treatment. One of these patients developed an apparent spontaneous cure, one remained stable without any increase in signs and symptoms, while another developed an apparent closure of the fistula following angiography; however, during this process, the patient developed ipsilateral visual loss. A fourth patient died without any particular treatment. In summary, it would appear that in untreated patients the potential for spontaneous cure is small, while the chances of static or increasing morbidity and mortality are significant.

Fatal Hemorrhage Sattler,⁴ in his review of 322 cases, found only six cases with fatal hemorrhage directly related to the CCF. Half of these were intracranial and the remainder related to epistaxis.

Static or Slowly Progressive Signs and Symptoms As noted above, the majority of untreated patients fall within this category. Undoubtedly, from the aspect of continued or slowly progressing morbidity, one should be encouraged to seriously consider an attempt at cure of this problem. Without question, the small, minimally symptomatic fistula in the elderly or the poor surgical risk patient may indicate a course of watchful waiting. In the majority of patients, some form of corrective therapy should usually be considered.

Definitive Treatment

General Principles When considering the management of an A-V fistula, the basic general surgical principles are those of obliteration of all arterial feeding vessels and additionally, if possible, obliteration of the venous drainage. One attempts to control both the inflow and outflow of the fistula and, if feasible, total excision of the lesion. Obviously, the critical location of a CCF negates consideration of this latter course of action. Gen-

Fig. 11—One case of severe orbital and lid edema found in CCF.

Fig. 12—Another case of severe orbital and lid edema found in CCF.

Fig. 13—Exophthalmus, chemosis and total EOM palsy found in CCF.

erally, the surgical attack upon a CCF has primarily been directed at the arterial feeding vessels.

Types of Management

Carotid Compression This type of approach toward controlling a CCF was used rather extensively in the 1800's. The basic approach was that of continuous carotid compression by a team of therapists in an attempt to eradicate the fistula by a thrombus forming within the compressed carotid artery. At times, this compression type of therapy would last for hours at end and, as one would anticipate, closure of the fistula was infrequent.

Fig. 14—Early lateral carotid angiogram in a case of CCF revealing prompt opacification of the cavernous sinus with minimal intracranial vascular filling.

Fig. 15—Lateral view carotid angiogram (arterial phase) in a case of CCF. Note the early and prompt opacification of the cavernous sinus and superior ophthalmic vein.

Venous Occlusion Direct injection of sclerosing agents into the superior ophthalmic vein has been tried in an attempt to thrombose the fistula. The literature generally indicates that this is not a particularly successful endeavor.

Cervical Carotid Ligation The next avenue of therapy essentially was that of an expansion of the carotid compression approach, i.e. ligation of the *extracranial* carotid artery. This obviously increased the potential for cure and in actuality around 40-60% of patients who had this type of treatment were either cured or improved. As noted earlier, one must bear in mind the possibility of worsening or precipitating cerebral ischemia through a siphoning effect of collateral blood flow into the fistula. In this situation, cerebral collateral blood flow is drawn toward the low pressure of the fistula and away from the cerebral hemisphere.

Intracranial-Extracranial Carotid Artery Occlusion (Trapping) In 1933, Hamby and Gardner⁶

Fig. 16—Early lateral carotid angiogram with "leakage" of contrast material into the cavernous sinus in the region of the carotid siphon.

Figs. 17 (top) & 18 (bottom)—AP and Lat. carotid angiograms in two cases of CCF. Note the dense opacification and enlargement of the cavernous sinus.

successfully treated a CCF using a combined intracranial approach. Their procedure consisted of an intracranial occlusion of the internal carotid artery just proximal to its posterior communicating branch and at the same time ligating the internal carotid artery in the neck. Rather ironically, this did not result in a cure due to persistent ophthalmic artery collateral flow into the fistula, however, the patient was much improved symptomatically. Following this initial case of Hamby, a number of patients began to be treated in this manner. This resulted in a higher cure rate, and symptomatic improvement obviating the problem of siphoning away collateral blood flow. Gradually, this combined approach in managing CCF

became an accepted procedure.

In 1942, Adson⁷ pointed out that a frequent reason for failure of fistula occlusion in a large number of these "Trapped" cases was related to continued feeding of the A-V fistula via the ophthalmic artery and its collaterals. Since this observation, a number of surgeons have stressed the importance of occluding this important small carotid branch when attempting to control a CCF

Figs. 19 (top) & 20 (bottom)—Lateral views of carotid angiogram in two cases of CCF. Note the early filling of the cavernous sinus and the venous drainage forward into the orbit.

Fig. 21—Lateral view of carotid angiogram (arterial phase) in a case (Fig. 5) of CCF. Note the opacification of the cavernous sinus and the rapid passage of contrast material into the sphenoparietal sinus, sylvian veins, and cortical veins near the sagittal sinus.

Fig. 22—VSM and lateral carotid angiogram views (early arterial phase) in a case (Fig. 10) of CCF. Note the opacification of both cavernous sinuses and the egress of contrast material into the contralateral petrosal sinuses and jugular outflow.

Fig. 23—AP & Lat. carotid angiogram views revealing prompt filling of the cavernous sinus and venous drainage posteriorly into the jugular outflow.

Fig. 24—Lateral postoperative skull Xray in case of CF (Figs. 5 & 21) demonstrating surgical clips on the carotid and ophthalmic arteries as well as two intracarotid muscle emboli tagged with silver clips. The patient had an uneventful course and was discharged neurologically normal in seven days.

In the past, surgical occlusion of the ophthalmic artery at its carotid origin had been considered with great trepidation because of possible retinal chemia. It was soon apparent that collateralization into the ophthalmic artery was present through the external carotid system and that this did not seem to be a particularly significant problem. The visual loss in CCF is probably unrelated to the surgical procedure, and has its inception prior to any attempted surgery.

An additional problem that one must constantly bear in mind in any surgical procedure directed toward the carotid artery relates to the problem of cerebral ischemia. As noted previously, the dangers of this problem are quite significant in those cases of *extracranial* carotid ligation due to the increased siphoning effect into the fistula. Where a one stage trapping procedure is carried out, the risks of this siphoning effect are obviated, but still present are the dangers of cerebral chemia due solely to the carotid occlusion. This may be particularly pertinent in the elderly patient who demonstrates angiographically no evidence of "crossover" through the anterior communicating artery.

Carotid Embolization In 1931, a surgical cure of a CCF was reported by embolization.⁸ That same year, Gardner⁶ used this same type of approach using a small muscle embolus. Other reports^{9,10} have described "controlled" embolization

techniques. Embolization is, of course, best preceded by an intracranial clipping of the carotid artery to prevent any distal migration of the embolus into the cerebral circulation (Figure 24). This basic approach, using either muscle emboli or other foreign material has proved to be increasingly popular for the management of CCF when coupled with the well accepted trapping procedure.

Direct Attack Several case reports¹¹⁻¹³ have appeared in the literature describing a direct attack on the CCF. The cavernous sinus is opened under direct vision and packed with muscle. Generally, these patients have had multiple surgical procedures with recurrence mainly through hypertrophy of the very small intracavernous branches (Figure 3). With this situation, the fistula is curable only with this type of approach.

Summary

The problem of CCF is relatively uncommon but not so unusual that it should be unfamiliar to the medical practitioner. The classical signs and symptoms of a CCF make the diagnosis quite apparent from clinical examination and one is only led to the diagnosis when one's clinical suspicion has arisen and if one searches for the associated findings. The suspected clinical diagnosis is quite easily confirmed by carotid angiography.

With specific regard to the management of CCF, it would seem that the surgical approach, when undertaken, should be vigorous in an attempt to cure the fistula with the first surgical endeavor, particularly since therapy in a stepwise fashion frequently does not result in cure and may compound the difficulty of later surgical approaches. In reviewing the various surgical methods of management, it would seem that occlusion of both the intracranial and extracranial carotid artery (trapping) is a logical approach to the problem and will result in a high rate of occlusion of the fistula. Efforts should be made to also occlude the ophthalmic artery since it may become an important later persistent feeder of the fistula. If the ophthalmic artery is not closed, consideration should then be made for embolization of the fistula through the internal carotid artery after its intracranial clipping.

Ophthalmia Neonatorum

Value of Prophylactic Treatment

W. BENTON BOONE, M.D.*; DONALD J. DOUGHMAN, M.D.*
and JOHN E. HARRIS, Ph.D., M.D.*

OPTHALMIA NEONATORUM due to *Neisseria gonorrhoeae* is still a classic example of oculo-genital disease. Due to the increase in the incidence of gonorrhea in recent years,¹ there is an increasing potential for gonococcal conjunctivitis in the newborn. This concerns not only obstetricians, but ophthalmologists, pediatricians and general practitioners as well.

As in other types of venereal disease, reported cases of genital gonorrhea represent only a small fraction of all cases. It is estimated that as many as two million new cases occur annually in the United States² and as many as 60 million new cases occur in the world.¹

The purpose of this paper is to report a recent case of Ophthalmia neonatorum seen by one of us (WBB) and to discuss the diagnosis, differential diagnosis and controversy regarding prophylaxis of this disease.

Case Report

A one-week old caucasian girl was seen because of increasing drainage from the right eye of three days duration. The 39-week gestation was complicated by maternal preeclampsia early in the third trimester, by *Trichomonas vaginitis* and by otitis externa. Maternal history was negative for venereal disease and a serological test for syphilis (VDRL) was negative. Labor was complicated only by premature rupture of membranes (36 hours prior to delivery). The birth weight was 3125 gms. 1% silver nitrate prophylaxis was recorded as being given in the delivery room within 30 minutes of delivery. A physical examination of the child was within normal

limits and she was discharged with her mother three days after birth.

The next day a small amount of drainage was noted from the right eye becoming profuse by the fifth day. On the sixth day the child was seen in an emergency room, a smear and culture taken of the conjunctiva, and sulfacetamide ophthalmic drops (10%) started for 'conjunctivitis'.

On the seventh day, the child was seen for the first time by one of us (WBB). A yellow-white, purulent conjunctival discharge was present on the right, and to a lesser extent on the left (Figure 1). On the right, there was edema and hyperemia of the eyelids, and chemosis and injection of the conjunctiva. The cornea was normal.

The smear taken the day before showed gram negative intracellular diplococci (Figure 2) confirmed bacteriologically as *Neisseria gonorrhoeae* one day later. A cervical smear and culture of the mother was positive for *Neisseria gonorrhea*. Repeated questioning of the mother brought out an admission of having been 'adequately treated for gonorrhea approximately one year ago.

Fig. 2—Gram stain of conjunctival smear from another case of gonococcal conjunctivitis. Gram stain x 300.

Fig. 1—Patient at day seven. Note purulent drainage coming from the right eye and swollen lids. Compare with figure three.

*Department of Ophthalmology, University of Minnesota, Minneapolis, Minnesota.

Supported by National Eye Institute, Grant #EY00027.

The child was treated with 300,000 units of CR Bicillin I.M. and 50,000 units of penicillin VK orally. Erythromycin ointment was given every two hours to both eyes.

Five days later, only minimal residual hyperemia was present (Figure 3) and the child was discharged from the clinic without further treatment.

Fig. 3—Five days after treatment. No drainage is present and no lid swelling.

Discussion

Historical Survey

After its discovery in the secretions of urethritis by Neisser in 1879,³ *Neisseria gonorrhoeae* was recognized as a cause of neonatal conjunctivitis, being found by numerous investigators.^{4,5} The introduction of prophylaxis by Credé in 1881 resulted in a significant decrease in the incidence of the disease.⁶ Before the use of silver nitrate 10% of babies born in the University Clinic in Leipzig had ophthalmia neonatorum. After the introduction of silver nitrate, the incidence dropped to 0.3%.⁷

With the introduction of staining techniques, such as the gram stain, other organisms besides gonococcus became associated with neonatal conjunctivitis. Stargardt⁸ and Heymann⁹ discovered

epithelial cytoplasmic inclusion bodies in some cases which are now called inclusion blennorrhea or inclusion conjunctivitis. Morphologically, these are identical with those inclusion bodies found in trachoma and are due to the large virus *Chlamydia oculogenitalis*.¹⁰

Perhaps as a result of the current "sexual revolution," inclusion conjunctivitis is now the most frequent type of neonatal conjunctivitis in the United States.¹⁰ Although inclusion conjunctivitis of the newborn has been considered a benign disease, recent reports of corneal and palpebral scarring have appeared.¹¹ And as chlamydial conjunctivitis often appears as a purulent papillary conjunctivitis it must be differentiated from gonorrheal ophthalmia.¹⁰ It should also be noted that Credé prophylaxis does not prevent inclusion conjunctivitis, nor does it effect staphylococci or other infectious agents which are ordinarily extragenital in origin.¹² Although many organisms have been isolated in neonatal conjunctivitis, (Table 1) many others are being added to the list. *Neisseria Gonorrhea*, *Chlamydia Oculogenitalis* and *Herpes Sim-*

plex virus Type 2 are the most frequent organisms genitally transmitted; however, *Mimcae*, *Candida*, and *Mycoplasma* have been reported as being transmitted genitally.¹⁰

TABLE 2

Agent	Time of Onset	Type of Onset
Silver Nitrate	Immediate	Subacute to Mild
Gonorrhoeae	3 to 5 days	Hyperacute
Staphylococcus	7 to 10 days	Acute to Mild
Inclusion	5 to 11 days	Hyperacute to Mild
Conjunctivitis		

Clinical Picture

Gonococcal ophthalmia neonatorum usually has a hyperacute onset three to five days postpartum. The amount of pus produced is so heavy that it must constantly be wiped away. Edema of the lids and conjunctiva are seen as part of this hyperacute picture. The vast majority of neonatal conjunctivitis with this florid picture are not due to *Neisseria gonorrhoea* but are due to inclusion conjunctivitis or staphylococcus aureus.¹³ Clinically, the differential diagnosis between these can be made by noting the time of onset postpartum, as seen in (Table 2). Note that conjunctivitis secondary to silver nitrate occurs early and is mild.

Diagnosis

In all cases, a newborn presenting with conjunctivitis should have smears done for gram and geisma stain and the secretions cultured on chocolate agar in 5-10% CO₂, an environment which, according to our microbiologist, supports *Neisseria* as well as all other aerobic bacteria.¹⁴ Conjunctival epithelial scrapings should be a part of the study since *Neisseria gonorrhoea* organism often appear in epithelial scrapings prior to being seen in smears of exudates.¹⁰

Epidemiology

Since this is not a reportable disease, the exact incidence of ophthalmia neonatorum is not known.¹⁵ The children of young unwed mothers from poor economic backgrounds are known to have a higher risk of developing ophthalmia neonatorum.¹⁶ Premature rupture of the amniotic membrane also predisposes the baby's eyes to infection, secondary to prolonged exposure to the organisms. The most dangerous type of confinement for the fetus is a protracted labor with face presentation.¹⁷ When all, or many of these factors are present, the index of suspicion of gonococcal ophthalmia

should be high.

Pathology

Anatomical considerations in the newborn influence greatly the manifestation of ophthalmia neonatorum. The absence of lymphoid tissue, the absence of tears at birth, and the lack of immunity in the neonate allow for a greater severity of infection and a variance in the clinical characteristics as compared to the adult.¹⁷

Prophylaxis

There is a controversy as to whether prophylaxis against ophthalmia neonatorum should be performed¹⁸ or whether prompt adequate treatment should be instituted with the onset of the disease. The most widely used form of prophylaxis in this country is 1% silver nitrate instilled in the eyes; and alternate forms include topical or parenteral penicillin prior to the development of the disease.*

Those who advocate no prophylaxis believe that the prompt response of ophthalmia neonatorum to treatment alleviates the need for troublesome and sometimes distressing prophylaxis. They point out that the availability of effective antibiotics in developed countries tremendously decreases the chance of blindness due to untreated ophthalmia neonatorum. In Britain where prophylaxis is not required, there has been no report of blindness from this cause.¹⁹ The other arguments for the discontinuation of silver nitrate revolve around the occasional mild chemical conjunctivitis occasionally produced with the 1% solution, and the catastrophic occurrence of the accidental substitution of the stronger ammoniacal silver nitrate preparations (25 to 35 percent).²⁰ One should also not forget that silver nitrate does not always work, as seen in this report.

Those who advocate continuation of Credé prophylaxis point out that successful therapy depends upon accurate diagnosis and treatment of the disease at its onset. Presently, many infants and mothers are discharged from the hospital observation before the incubation period of dangerous organisms has passed. This coupled with the increasing incidence of asymptomatic gonorrhea in prenatal women²¹ and the present recognition of asymptomatic G.C. in men²² builds a strong case for the continuation of prophylaxis by the Credé silver nitrate methods. Recognition is also made of the fact that in some of the newer countries

*Penicillin is probably the most effective of the substitute forms of prophylaxis,²³ however, the fears of patient sensitization and/or the production of resistant bacteria may be well founded.

where adequate treatment is not available, silver nitrate has a place in preventing gonorrhea as a cause of blindness.

The current conclusion regarding prophylaxis is that although gonorrheal ophthalmia neonatorum can be successfully treated, most consultants

in this country recommend prophylaxis with 1% silver nitrate solution in wax ampules (to prevent water evaporation and concentration of the solution), with topical penicillin preparations as alternatives.²³

Hennepin County Academy of Family Physicians

The Hennepin County Academy of Family Physicians' Annual Invitational Banquet will be held Thursday, November 15, 1973, at the Sheraton Ritz Hotel in downtown Minneapolis. A social hour at 6:00 P.M. with dinner scheduled at 7:30 P.M. The speaker will be Dr. Herb True, a multifaceted idea man and humorist, currently the senior lecturer for the American Management Association and the Presidents Association. Dr. True's presentations feature a rapid-fire staccato of provocative ideas. Physicians and their guests, both from the metropolitan and out-of-state areas, are invited. Contact: Alan K. Schultz, M.D., 5920 Kirkwood Circle, Minneapolis, Minnesota 55442, telephone 537-8853.

Minnesota Academy of Family Practice

Minnesota Academy of Family Practice announces it's Third Midwinter Seminar January 26th to February 2, 1974 in the Caribbean. Info; MAFP, 214 East Main, Waterville, Minnesota, 56096.

Clinical and Invasive Studies of Coronary Artery Disease*

One-Year Follow-up of 505 Patients

CHARLES R. PETERSON, M.D.†

MOST REPORTS CORRELATING coronary arteriographic findings with clinical diagnosis or prognosis do not compare patients selected for arteriography with similar patients who did not have arteriographic studies.¹⁻⁴ Comparative follow-up of patients who have arteriographic studies with larger groups of similar patients from which they were selected might provide additional information about the effective use of both non-invasive and invasive techniques.

This report reviews the selection of 133 patients for coronary arteriography from 505 patients consecutively evaluated for coronary artery disease.

Patients and Methods

The purpose of this study is to review the

Section of Cardiology, Department of Internal Medicine, St. Louis Park Medical Center, Minneapolis, Minnesota.

*Supported by the St. Louis Park Medical Center Research Foundation.

See editorial, page 968.

diagnosis and management of patients with known or suspected coronary disease by obtaining periodic morbidity and mortality data after prospective classification into diagnostic groups. Patients were evaluated and classified *prior to* arteriography. The accuracy of the clinical classification compared with the arteriographic and other findings obtained in those patients selected for invasive procedures.

Patient Selection and Classification

Five hundred and five patients under the age of 70 consecutively evaluated because of suspected or proven artery disease (CAD) were classified prospectively into various diagnostic groups on the basis of clinical evaluation. The average age of the 390 men was 52, and of the 115 women, 54 years. The diagnostic categories and description of the patients in each group are listed in Table 1. Patients with other significant cardiopulmonary conditions (valvular disease, emphysema, heart failure of unknown cause, etc.) and patients with peripheral occlusive vascular

TABLE 1

Diagnostic Classification: Coronary Artery Disease (CAD)

Group I. Doubtful CAD

- (A) NO CAD: Very atypical symptoms or findings; ECG normal or with minor, non-specific abnormality; negative exercise ECG.
- (B) POSSIBLE CAD: Atypical but suspicious symptoms; ECG normal or with non-specific abnormality; negative exercise ECG.

Group II. CAD—Asymptomatic or Class 2 Angina

Previous myocardial infarction, now asymptomatic; angina predominantly with exertion more than normal, non-strenuous daily activities (with or without previous infarction); angina stable, promptly relieved with rest; normal or abnormal exercise ECG; no evidence of heart failure or cardiomegaly.

Group III. CAD—Class 3 or 4 Angina

Frequent angina with normal, non-strenuous daily activities, usually requiring several nitroglycerin per day; rest or nocturnal angina; hospital admission for acute coronary insufficiency without infarction (even if usually Class 2 angina); normal or abnormal exercise ECG; no evidence of heart failure or cardiomegaly.

Group IV. CAD With Heart Failure

Previous documented myocardial infarction or typical angina with persistent cardiomegaly in spite of digitalis and diuretic therapy; usually Class 2-4 dyspnea with or without angina; may have significant papillary muscle dysfunction or ventricular aneurysm.

isease or hypertension without clinical evidence of CAD, were excluded.

The emphasis in this report is on those patients without significant cardiomegaly or heart failure (Groups I-III). Most of the patients in Groups I-III were evaluated for chest pain or abnormal electrocardiograms. An attempt was made to describe the symptoms as typical, suspicious, or atypical of angina pectoris. Patients with diagnosed CAD (previously documented myocardial infarction, abnormal exercise ECG, or typical angina pectoris) were divided into two groups according to the severity of symptoms. Most of the patients with Class three or four angina had a therapeutic trial with propranolol and long-acting nitrate drugs. This usually resulted in some improvement in symptoms but usually not enough to reclassify the patients as functional Class one or two. These drugs were discontinued 2 hours prior to arteriography and invasive hemodynamic measurements. Most of the patients were not receiving anticoagulant medication.

Sixty-five patients were seen initially because of acute myocardial infarction documented by acute ECG changes and enzyme rises. The 60 survivors were included in Groups II-IV on the basis of clinical evaluation three to six months later. These patients were advised to increase activity gradually to full days of nonstrenuous activity in three months. If asymptomatic at this time, they were encouraged to attempt gradual further increases in exercise or activities.

Exercise Electrocardiography

Exercise electrocardiography was performed on a patient-propelled or motorized treadmill. If the patient developed significant chest discomfort or telemetry ECG changes in less than five minutes, exercise was terminated. The exercise was increased after three minutes if a minimum heart rate of 140/minute was not achieved. The average heart rate was 71 before exercise, 143 peak rate during exercise, and 122 on the immediate post-exercise ECG. The test was considered abnormal if the S-T segment depression was one mm or more and the depressed segment was horizontal or sloping downward. If the control tracing had S-T or T abnormalities, two mm depression was required for an abnormal response. Equivocal changes were considered normal for the purpose of this report.

Indications for Coronary Arteriography

Patients with doubtful CAD (Group I) had

selective coronary arteriography performed only if an accurate diagnosis was considered important because of ominous but non-diagnostic symptoms, psychological considerations, or administrative reasons. Patients with definite but minimally asymptomatic CAD (Group II) had selective coronary arteriography recommended primarily because of young age (under 50), rare occasions of angina more severe or prolonged than usual, or other symptoms (such as syncope or nausea). Most patients with Class three-four angina (Group III) were advised to have selective coronary arteriography performed with the understanding that revascularization surgery should be considered. Selective coronary arteriography was performed by the percutaneous femoral approach in 90% and by trans-brachial in the remainder.

Physiological Studies

Measurement of rest and exercise left ventricular pressures at the time of coronary arteriography was employed only in the latter part of this series. Resting left ventricular end-diastolic pressure (LVEDP) was measured and average exercise LVEDP was measured during the first two respiratory cycles immediately after three minutes of exercise.

Individual LVEDP values were measured 0.04 second after the onset of the QRS of the ECG (0.06 second if left bundle branch block was present). The LVEDP values in this report were measured after selective coronary arteriography but before ventriculography. It is possible that better correlations may have been obtained had the measurements been made before arteriography, but the control patients were studied identically for comparison. A comparison of the change of LVEDP with exercise before and after arteriography in 12 patients showed no difference. Ten randomly selected patients also had cardiac output measurements to define the average hemodynamic change with exercise. The mean (± 1 SD) changes from rest to exercise were: heart rate increase from 78 ± 9 to 101 ± 10 ; oxygen consumption/min/M² increase from 135 ± 26 to 322 ± 82 ; cardiac index increase from 2.9 ± 0.4 to 4.1 ± 0.9 .

Invasive Data Classification

To permit diagnostic comparison with clinical Groups I-III, the patients who were studied by arteriography were classified into three groups on the basis of the number of the three main coronary systems which had greater than 50% narrowing

of at least one area of the proximal arterial segments (none, single, or multiple vessel disease). Greater than 35% occlusion of the left main coronary artery was considered multiple vessel CAD. Over 90% of the patients in Groups II and III had at least one vessel with greater than 75% narrowing. All patients had cine arteriograms and most of them also had serial or spot filming of both right and left coronary systems in at least two projections.

Those patients who had rest and exercise LVEDP measurement also were classified into three groups with exercise LVEDP increases of less than 5 mm Hg, 5-10 mm Hg, or greater than 10 mm Hg. This classification was based in part on the findings of a previous study.⁵ The average LVEDP values at rest prior to exercise for all three groups of patients were between 10 and 12 mm Hg.

Revascularization Surgery

Although the statistics of patients selected for arteriography or revascularization generally represent the criteria of the author, a number of patients refused recommendations for arteriography or surgery. During the period that patients entered the study, an increasing proportion of patients with Class three or four angina pectoris (Group III) accepted recommendations for revascularization surgery utilizing the reversed saphenous vein technique. This report has approximately equal numbers of patients in Group III treated with and without surgical revascularization, but strict comparison is not valid because of the small sample, the lack of random selection, and an average time delay of several months be-

tween evaluation and revascularization surgery (representing a period of medical treatment).

Follow-up Methods

Follow-up information was obtained by direct physician evaluation in about 40% of the patients and by mailed questionnaire or telephone in the remainder. The study is designed to obtain follow-up data one, three, and five years after initial evaluation and one-year follow-up has been 98% complete. Most of the patients lost to follow-up were from Group I.

Results

The number of patients in each of the diagnostic groups and subgroups is shown in Table 2. The percentage of patients with abnormal exercise ECG's, abnormal coronary arteriograms, and abnormal increases in exercise LVEDP measurements was greatest in the patients most symptomatic with angina pectoris (Group III). The more typical and severe the findings of coronary artery disease, the greater the percentage of patients who were studied by selective coronary arteriography (14% of group I, 21% of Group II, and 70% of Group III).

Selective coronary arteriography reversed the clinical diagnosis in five patients. Two patients had false negative clinical diagnoses of coronary artery disease (including normal rest and exercise electrocardiograms) reversed by arteriographic studies. Both were studied because of syncope of unknown cause.

Three false positive diagnoses of coronary artery disease reversed by selective coronary arteriography were in women with atypical symptom

TABLE 2
Clinical and Invasive Studies of Coronary Artery Disease (CAD):
505 Patients

Group	Diagnosis	Number of Patients	Exercise ECG		Coronary Angio	
			Normal	Abnormal	Normal	Abnormal
I	Doubtful CAD					
A	No CAD	158 (0)	129 (0)	8 (0)	
B	Possible CAD	70 (1)	31 (0)	21 (0)	2 (0)
II	CAD: Minimally Symptomatic					
A	Medical Treatment	158 (2)	30 (1)	20 (0)	3 (0)	29 (0)
B	Surgical Revasc.	2 (0)	1 (0)	1 (0)		2 (0)
III	CAD: Class 3-4 Angina Pectoris					
A	Medical Treatment	45 (9)	3 (0)	8 (4)	..	18 (7)
B	Surgical Revasc.	46 (5)	6 (0)	27 (2)	46 (5)

TOTALS		505 (25)	200 (1)	56 (6)	32 (0)	101 (13)

The numbers in parentheses indicate the number of deaths within one year of initial evaluation.

who had 1 mm ST depression on post-exercise ECG's. An additional patient not included in this series because of recent study with short follow-up had ECG and vector-cardiographic evidence of an old anterior myocardial infarction, but selective coronary arteriography demonstrated normal coronary arteries.

Risk Factors

Although the risk factors of family history, cigarette smoking, obesity, hypertension, diabetes, and hyperlipidemia increase the statistical likelihood of a patient having coronary artery disease,⁴ these factors alone were not considered enough to justify labeling a patient with this diagnosis in the absence of typical symptoms or specific ECG abnormalities. Many of the patients in Group I had one or more risk factors which constituted part of the reason for cardiac evaluation.

Table 3 lists the mean cholesterol and triglyceride values in those patients who had selective coronary arteriography. The mean values were highest in patients with coronary artery disease. However, the overlap of individual determinations was so great as to be of little help in diagnosis in an individual patient. The other risk factors, alone or in combination, were of equally limited value for this purpose.

TABLE 3

Mean Cholesterol and Triglyceride Values in Patients Studied by Selective Coronary Arteriography

	Age (years)	Cholesterol (mgm %)	Triglyceride (mgm %)
No CAD (32 patients)	50 ± 11	221 ± 50	187 ± 41
Single Vessel CAD (36 patients) p	50 ± 8 NSD	236 ± 45 NSD	205 ± 104 NSD
Multiple Vessel CAD (60 patients) p	54 ± 8 NSD	265 ± 59 <.001	211 ± 90 NSD

p = The probability of no significant difference (NSD) between the means (±1 SD) and the control group (No CAD).

Noninvasive vs Invasive Correlations

Table 4 displays the relationship of clinical diagnostic Groups I-III to the arteriographic findings in 133 patients. Many of the patients in Group I were studied because of the relatively young age at which coronary disease had been diagnosed and were found to have one occluded vessel related to a previous myocardial infarction with only minimal disease in the remaining coronary arteries. Seventy-three percent of the patients who had coronary artery disease but were minimally symptomatic (Group II) had single vessel coronary disease, and 85% of the patients with moderate or severe angina (Group III) had multiple vessel disease.

TABLE 4
Clinical vs Arteriographic Correlation: 133 Patients

	1 0 Vessel	2 1 Vessel	3 2-3 Vessel
I. No CAD	29	1	1
II. CAD: Mild Symptoms	3	27	7
III. Angina: Class 3-4		10	55

Groups I-III indicate clinical classification prior to selective coronary arteriography.

Groups 1-3 indicate arteriographic classification based upon the number of main coronary artery systems with greater than 50 percent narrowing of proximal segments.

Table 5 displays the relationship of the clinical groups of patients to the number of patients with different levels of LVEDP increase with exercise. The percentage of patients with a rise of LVEDP with exercise of greater than 4 mm Hg increased from 10% in Group I to 46% in Group II and 88% in Group III. Similarly, the percentage of patients with an exercise LVEDP rise greater than 10 mm Hg increased from five percent in Group I to 17% in Group II and 60% in Group III. Since the clinical grouping included some patients with false positive and false negative clinical diagnoses as determined by subsequent arteriography, slightly better correlations of exercise left ventricular dysfunction could be

TABLE 5
Clinical vs Exercise LVEDP
Correlations: 84 Patients

	1 <5 mm Hg	2 5-10 mm Hg	3 >10 mm Hg	Average LVEDP RISE
I. No CAD	18	1	1	2 ± 5
II. CAD: Mild Symptoms	13	7	4	5 ± 5 p = NSD
III. Angina: Class 3-4	5	10	25	13 ± 8 p = <.001

Groups I-III indicate clinical classification prior to coronary arteriography. LVEDP groups indicate the rise of left ventricular and end-diastolic pressure with supine exercise at the time of arteriographic studies.

p = probability of no significant difference (NSD) of the means (±1 SD) from the control group (I).

made with arteriographic rather than clinical groupings of patients.

These results indicate a relationship of the activity and circumstances that provoke angina with both the severity of arteriographically demonstrable CAD and physiological evidence of left ventricular dysfunction.

Morbidity and Mortality

Much of the follow-up information was obtained indirectly or by mailed questionnaire so the true incidence of myocardial infarction and true cause of death in some cases are not known. Accurate comparison of Group III to the other groups is not possible since about one-half of the patients in this group had revascularization surgery. Despite these limitations, information obtained by the first year follow-up survey is instructive. Table 2 lists the diagnostic groups with the number of deaths within one year indicated in parenthesis.

The one death which occurred in the group of 228 patients with doubtful CAD (Group I) was in a 57-year-old woman with left bundle branch block evaluated for abdominal discomfort of unknown cause. She died at home two months later, and there were no clues to the possible cause of death.

Two deaths occurred in the group of 160 patients with minimally symptomatic CAD (Group II). One patient was an asymptomatic 65-year-old man who had a myocardial infarction five years before and had a negative exercise ECG. He died suddenly at home eight months after evaluation. The other patient was a 50-year-old man who had an inferior myocardial infarction five years before and was asymptomatic. He had not had a recent exercise ECG. Engaged in an exercise program at a sports and health club, he collapsed suddenly on a treadmill and was dead on arrival at the hospital. Autopsy demonstrated an old occlusion of the right coronary artery and a fresh thrombus in the anterior descending coronary artery beginning at a small and minimally occluding atherosclerotic plaque.

There were nine deaths within one year in the group of 45 patients with moderate or severe angina who did not have revascularization surgery (Group III-A). Seven of these patients had been hospitalized for coronary insufficiency without myocardial infarction within six months of death, and seven of the nine patients had multiple vessel

CAD demonstrated by selective coronary arteriography. Coronary arteriography for consideration of possible revascularization surgery had been recommended to all nine patients.

In the 48 patients who had revascularization surgery, there were five deaths within one year (four hospital deaths following surgery and one late death). All but two patients had Class 3-4 angina pectoris at the time of surgery, and four patients had simultaneous resection of large area of akinetic myocardial scar. The average number of saphenous vein grafts per patient was 2.2. Five of six patients who had angiographic studies 13-24 months after surgery had patent revascularization vein grafts.

There were eight deaths within one year in the 26 patients with CAD and heart failure (Group IV). Only two patients from Groups I-III were known to develop heart failure or cardiomegaly within one year of initial evaluation and both patients were from Group III.

In the total study group there were 16 documented non-fatal myocardial infarctions within one year of the initial evaluation, and all 16 cases occurred in clinical Groups II, III, and IV. Five of the 158 patients (three percent) who were minimally symptomatic at the time of initial evaluation (Group II) had non-fatal myocardial infarctions within one year. Nine of the 45 patients (20%) who had Class 3-4 angina treated medically (Group III-A) had non-fatal myocardial infarctions within one year. One late, non-fatal myocardial infarction occurred in one of the patients who had revascularization surgery, and another myocardial infarction occurred in a patient with CAD and heart failure.

The known one-year morbidity and mortality statistics in this study indicate that the highest risk patients are those who are the most symptomatic with angina, have abnormal exercise ECG, and have multiple vessel coronary artery disease with greater than 50% occlusion demonstrated by selective coronary arteriography.

Discussion

In this series of 505 consecutive patients evaluated for suspicious or proven CAD, the clinical diagnosis was determined primarily by two non-invasive techniques: the history and the electrocardiogram. Other clinical and laboratory information, although considered important, was not decisive in classifying the patient into one of the

four categories.

Patients were selected for coronary arteriography primarily because of the nature and circumstances of symptoms. Most of the patients considered clinically to have doubtful or minimally symptomatic CAD had arteriography performed because there was some degree of psychological or administrative incapacitation, or because there were ominous but non-diagnostic symptoms that otherwise were unexplained. Most of the patients with Class 3-4 angina had arteriography because there was apparent symptomatic incapacitation or a recent change in symptoms suggestive of impending myocardial infarction. Consideration for possible revascularization surgery therefore was indicated.

There are reasons to be skeptical about the usefulness of a subjective interpretation of symptoms. Objective laboratory results usually are more reliable and reproducible, and combinations of multiple selected results can increase the probability of the presence of significant CAD.⁴ Other studies have demonstrated that the placebo effect of medical or surgical treatment makes the subjective evaluation of the relief of symptoms unreliable.⁶⁻⁸ However, it should not be assumed that an accurate description of symptoms is of equally limited value for diagnosis or prognosis, especially if the effects of current treatment on symptoms are considered. A patient with a high number of risk factors may be years away from a major coronary event, while a patient with typical severe angina may have greater imminent risk in spite of many normal noninvasive test results.

The results of this study suggest that a careful description and functional classification of symptoms may be the most important noninvasive means of determining imminent risk of CAD, should be a major consideration in selecting patients for diagnostic procedures, and may allow separation of patients with similar arteriographic findings into relatively high and low risk groups.

In the 228 patients in this study with doubtful CAD (Group I), there was one known death within one year of the initial evaluation, and the cause of death in this patient was not known. This patient was not included in the 31 patients in Group I who had selective coronary arteriography. However, it is unlikely that performing invasive procedures on all of these patients with atypical symptoms for consideration of revascularization surgery would prevent many deaths.

In the 203 patients with clinically proven CAD without significant heart failure or cardiomegaly who did not have revascularization surgery (Groups II-A and III-A), there were 11 deaths within one year (5.4%). This mortality rate is similar to that of other large series of similar patients.⁹⁻¹¹ By prospective clinical evaluation by noninvasive means, these 203 patients were divided into a minimally symptomatic group with a one-year death rate of 1.5% (Group II-A) and a significantly symptomatic group with a one-year death rate of 20% (Group III-A). Even considering the difficulties and the sometimes arbitrary nature of a subjective evaluation of symptoms, this suggests that symptoms alone should allow a clinical separation of patients with known or suspected CAD into two groups of less than five percent annual mortality and greater than 10% annual mortality. Although the selection of patients for selective coronary arteriography should always be individualized, Class 3-4 angina pectoris without diffuse myocardial failure should constitute a definite indication for selective coronary arteriography for consideration of possible revascularization surgery.

A negative exercise electrocardiogram does not exclude the diagnosis of coronary artery disease, but it helps place the patient in a low risk category, especially if symptoms are atypical or mild. Diagnostic and prognostic priority should be placed on symptoms if angina is typical and severe, even if an exercise electrocardiogram is normal. An abnormal exercise electrocardiogram favors a high risk situation. However, if the patient has minimal symptoms, close medical follow-up may be preferable to surgery, especially if arteriography is performed and demonstrates single vessel coronary artery disease.

The reversed saphenous vein revascularization can produce satisfactory relief of angina pectoris associated with demonstrated graft patency for at least a year in most cases.^{12,13} The ideal indications for surgery involve a number of technical and functional considerations that must be evaluated by invasive techniques.¹²⁻¹⁴ The long term morbidity and mortality are not yet known. Occlusive pathology of the vein graft, the anastomoses and the distal coronary arteries have been shown to compromise the results of surgery.¹⁴⁻¹⁶

To establish that revascularization surgery will affect the natural course of coronary artery disease favorably, it should be demonstrated in large

groups of patients that the mortality is significantly less than similar groups of patients which have been classified arteriographically. The annual mortality rate in previous reports varies from two to ten percent depending upon the number of coronary systems with significant narrowing.¹⁻²

The follow-up survey of all the patients in this study with arteriographically proven significant coronary artery disease who did not have revascularization surgery indicated a mortality within one year of 20%. Considered alone, this fact would appear to be enough to justify liberalizing the indications for arteriography and revascularization surgery. However, the mortality within one year in all patients with atypical or minimal symptoms without cardiomegaly (Groups I and II) was less than one percent. Furthermore, in the entire study group, all but one of the deaths which were known to have been due to coronary artery disease were identified as high risk by noninvasive techniques prior to death. The results of this study therefore do not justify the conclusion that most of the 505 patients should have been studied

arteriographically.

The severity of angina pectoris defined by frequency and provoking circumstances is a significant predictor of the pathophysiology and natural history of patients with chronic coronary artery disease. Patients with episodic angina at rest or frequent angina induced by normal, nonstrenuous daily activities have a much greater likelihood of multiple vessel coronary artery disease, exercise induced left ventricular dysfunction, and death or acute myocardial infarction within one year than do patients with atypical or minimal symptoms. A careful description of the severity of angina therefore is an important noninvasive means of identifying the high risk patient with coronary artery disease. The patients most symptomatic with angina may be most likely to benefit from revascularization surgery.

Acknowledgment

The author acknowledges the help of Miss Barbara Brekke, Mrs. Lorraine Lockrem, and Mrs. Elaine Anderson in contacting patients for follow-up and helping with preparation of the manuscript. Mr. Terry Gunther did the statistical analyses.

Cerebrovascular Malformations in Hereditary Hemorrhagic Telangiectasia

BLANKA SCHAUMANN, Ph.D.* and MILTON ALTER, M.D., Ph.D.*

HEREDITARY HEMORRHAGIC telangiectasia (HHT) is an autosomal dominant disorder characterized by familial occurrence of multiple capillary and venous dilations (telangiectatic lesions) of the skin, mucous membranes and internal organs. The telangiectases are rare in childhood and become more frequent with advancing age. Recurrent bleeding may occur from these lesions. The most common manifestation is epistaxis and careful inspection of the nasal mucosa and mouth after adolescence usually reveals punctate telangiectatic lesions.

The expression of the disease is variable and many organ systems may be affected including the skin, eyes, lungs and gastrointestinal tract. There have also been reports of central nervous system (CNS) involvement, but most of them, unfortunately, have not been well documented. In spite of the scarcity of confirmed cases, vascular anomalies in the CNS may actually be quite common. Not infrequently, the patients and other members of their family are described as suffering from headaches (Goldstein, 1930;¹⁵ Campbell, 1944;⁶ Walton, 1953;²⁸ Smith, Bartholomew, and Cain, 1963;²⁵ Myles, Needham, and LeBlanc, 1970;²¹ paralysis (Hodgson, Burchell, Good, and Clagett, 1959;¹⁷ Myles *et al.*, 1970),²¹ vertigo, slurred speech (Michael and Levin, 1936),²⁰ "fits" (Hodgson *et al.*, 1959;¹⁷ Bloom and Moynahan, 1960),² convulsive seizures (Michael and Levin, 1936;²⁰ Williams and Flink, 1947),³⁰ personality changes (Walton, 1953),²⁸ "brain fever" with loss of speech and impaired hearing (Lawless, 1934),¹⁸ premature cerebrovascular accidents (Goldstein, 1921;¹⁴ Hodgson *et al.*, 1959),¹⁷ "meningeal bleeding" (Saunders, 1962),²⁴ "meningitis" (Myles *et al.*, 1970),²¹ "a ruptured blood vessel of the brain" (Cobb, 1915;³ Mekie, 1927;¹⁹ Goldstein, 1930),¹⁵ or a "brain tumor" (Michael and

Levin, 1936).²⁰ An abnormal EEG has also been reported (Bloom and Moynahan, 1960).²

A typical example of central nervous system involvement in the family of a patient with HHT is given by Walton (1953).²⁸ The patient suffered from occipital headache, generalized convulsions and spastic paraplegia. His mother had HHT. The maternal grandmother died from a "stroke" at age 32, a brother from epilepsy at 39, and a sister of cerebral hemorrhage after suffering epistaxis for several years.

The possibility that abnormal vessels in the brain were responsible for the neurological disturbances has been considered by some authors. Thus, Campbell (1944)⁶ suggested that intracerebral telangiectasis might have caused the migrainous attacks in one of his patients with HHT. Bloom and Moynahan (1960)² thought that a hemorrhage from abnormal intracranial vessels might have explained the fits in two members of a family with HHT. A case of HHT with a cerebral hemorrhage resulting in hemiplegia was described by Goldstein.^{14,15} Also Myles *et al.* (1970)²¹ described a family with transient neurologic symptoms and considered the possibility of bleeding from cerebral telangiectases as the cause of the alternating hemiparesis in their patient.

Only a few articles described the central nervous system in HHT in sufficient detail to determine the type of vascular pathology present. Most of these reports describe capillary telangiectases of the brain (Michael and Levin, 1936;²⁰ Werner, 1942;²⁹ Snyder and Doan, 1944;²⁶ Ytrehus, 1948;³¹ Brinkmann, 1950;⁵ Vischer, 1951;²⁷ Zelman, 1962;³² Heffner and Solitare, 1969)¹⁶ but it is not always clear where the lesions are within the brain substance or leptomeninges.

Larger cerebral vascular malformations in HHT have also been recognized. In an autopsy of a Negro man with bifrontal headaches and convulsions, Heffner and Solitare (1969)¹⁶ found several telangiectatic lesions on the cut surface of

*Epidemiology and Genetics Unit, Department of Neurology, University of Minnesota and the Minneapolis Veterans Administration Hospital, Minneapolis, Minnesota.

the brain. The largest of them, which measured 40 mm in greatest dimension, was in the right frontal lobe and involved both the gray and white matter. Similar telangiectases were seen in the pons and cerebellum. Cohn and Rosenthal (1948)⁹ described a case of HHT with a venous angiomatous malformation of the spinal cord disclosed at operation. Quickel and Whaley's (1967)²² patient suffered from severe frontal headaches and was found to have had a subarachnoid hemorrhage. Arteriography revealed a capillary angioma in the left caudate nucleus. Courville (1957)¹⁰ reported clusters of enlarged and tortuous veins and telangiectatic lesions in the leptomeninges on microscopic study. The autopsy of Bird and Jaques' (1959)¹ case showed thin-walled veins. The malformation spread widely in the white matter but was particularly concentrated in the subcortical areas. Reagan and Bloom (1971)²³ presented another case with multiple venous angiomas of the left cerebrum found on autopsy of a patient with HHT and seizures. A large venous temporo-parietal angioma was detected angiographically in the brain of a patient described by Giampalmo, Badini, and Buffa (1971).¹³

Only three reports record larger arteriovenous (AV) malformations of the CNS in HHT. Boczko (1964)³ described a patient who, several years after surgery for multiple pulmonary AV malformations, was discovered to have an AV malformation in the left cerebral hemisphere. The angiogram showed a cluster of small vessels, 10-15 mm in greatest diameter, in the anterior parietal area. The neurological symptoms included a convulsive seizure associated with loss of consciousness of unknown duration and followed by numbness and transient right hemiparesis. Chandler's (1965)⁷ patient suffered from severe headaches, seizures and transient losses of consciousness and was found to have a large AV fistula, "the size of a thumb," involving the vein of Trolard. Czernobilsky and Bouzarth (1965)¹¹ reported a patient with frontal headaches, nuchal rigidity, diplopia and the right facial hyperaesthesia. At autopsy, a subarachnoid hemorrhage was found over the right frontal, parietal, and temporal lobes, the base of the brain and the cerebellum. The cerebral vascular malformations consisted of a ruptured aneurysm of the circle of Willis at the junction of the right internal carotid and middle cerebral arteries and an arteriovenous angioma in the mid-

Fig. 1—A lateral angiogram illustrating a large arteriovenous malformation in the left fronto-parietal area of a 46-year-old man with hereditary hemorrhagic telangiectasia.

Fig. 2—An anteroposterior view of the same patient.

brain. There was histologic evidence of recent hemorrhage in the surrounding brain tissue.

Recently, a possible fourth case of a cerebral AV malformation in HHT has been reported (Boynton and Morgan, 1973).⁴ The patient was a female infant with a family history of HHT in several consecutive generations. The patient's father had an angiomatous malformation surgically removed from the spinal cord. The child died in progressive congestive heart failure attributed to a large AV malformation involving the quadrigeminal region of the brain stem. There were no telangiectases on postmortem examination. Since telangiectases usually become apparent only after puberty, failure to detect them at autopsy in this infant did not preclude the diagnosis of HHT.

In view of these reports, it is clear that the genetic defect which results in abnormal formation of vessels in HHT does not spare the CNS. The comparative rarity of documented reports of CNS involvement, however, prompted us to report our experience. Our case represents only the fourth or possibly the fifth documented example of a large vascular malformation in the CNS associated with HHT.

Case Report

A 46-year-old male truck driver was admitted to the Minneapolis Veterans Administration Hospital with a history of focal seizures. When he was 11 years old, he had a head injury and seizures developed thereafter. The seizures started with spasms in the right foot, ascended to the leg and thence to the chin, being followed by loss of consciousness. As a child he had frequent nose bleeds. Several relatives in four consecutive generations also had frequent epistaxis and some had gastrointestinal bleeding. Small blood vessel tumors had been observed on the lips of the family members with a tendency to epistaxis.

On auscultation of the skull, a bruit was audible over the left parietal area. Punctate vascular lesions were noted on the lips, buccal mucosa and tongue. The chest, heart and abdomen were normal. There was a moderate decrease in muscle strength on the right, a right Babinski sign and left-right confusion.

A hemogram, urinalysis and electrocardiogram were normal. X-rays of the chest, upper gastrointestinal tract and an intravenous pyelogram were normal but an X-ray of the skull showed a large, calcified left parietal mass. The electroencephalogram was normal. Bilateral carotid angiograms revealed a large cavernous hemangioma in the left parietal area with smaller hemangiomas in the right frontal area. The hemangioma was fed by vessels from both sides of the head. Intelligence measured by the Wechsler Adult Intelligence Scale showed an IQ of 82. Surgery for the hemangioma was declined.

The patient was treated with diphenylhydantoin and mephobarbital with good control of seizures.

He was readmitted to hospital six years later because of increasing difficulty in walking and an increase in seizures. He had deteriorated mentally in the interim and appeared thinner. Bruits were present over both carotid arteries as well as in the left temporal area. Small capillary hemangiomas were noted on the tongue, lips and buccal mucous membranes. They were also present on the trunk. He had a spastic right hemiparesis with right hyperreflexia. Sensation was normal.

A shift of the midline structures was seen on the echoencephalogram. A four-vessel angiogram showed a large AV malformation in the left frontal-parietal area (Figures 1 and 2). It took approximately five seconds from arterial to venous filling. The major feeding vessels included the posterior fronto-parietal branch of the left middle cerebral artery, both anterior cerebral arteries and a parieto-occipital branch of the left posterior cerebral artery. A smaller AV malformation was noted in the right frontal pole supplied by the callosal-marginal branch of the anterior cerebral artery. The electroencephalogram showed a grade 1 abnormality with delta showing in the left parietal area.

The anticonvulsant medication was adjusted and he became free of seizures. Because of the size of the malformation and its extensive network of feeding vessels, he was not thought to be a good surgical risk and he was discharged to a nursing home.

Discussion

The paucity of reports of vascular malformations in the CNS in HHT may be attributed to several factors. Larger anomalous lesions of the brain may, in fact, be rare in HHT (Courville, 1957).¹⁰ Clinical and neuropathologic evidence suggests that telangiectases in the CNS are usually silent (Boczko, 1964)³ and therefore may not draw any attention to their presence in living individuals. In a number of autopsies performed in instances of HHT, the brain is not examined. In others, the examination of the brain is very cursory and limited to gross inspection. Neurological manifestations may also be attributed to complications of pulmonary AV malformations (Dyer, 1967).¹² Although many patients with HHT have symptoms referable to the CNS such as headaches, convulsive disorders, loss of consciousness, mental confusion and premature strokes, cerebral angiography is apparently rarely performed. Whether neurological symptoms in a given patient with HHT are due to a cerebral vascular malformation can be determined by appropriate contrast studies and a high order of suspicion is warranted. Earlier recognition of such malformations may make surgical treatment feasible.

Summary

Neurological symptoms in hereditary hemorrhagic telangiectasia (HHT) are not unusual but the presence of a vascular malformation involving the nervous system has been documented in only a few cases. The majority have been reported in the last decade suggesting that neurological in-

volvement in HHT is now being recognized more often and may be more common than is implied by the few published reports. An additional patient with HHT is presented in whom a large vascular malformation of the brain was demonstrated. The literature on HHT with confirmed cerebral vascular lesions is reviewed.

Medical Student

Robert J. Ingli, a second year student at the University of Minnesota Medical School, received an award of a \$160 set of illustrated medical texts for community service from the CIBA Pharmaceutical Company.

Ingli was nominated by his classmates for his involvement in several community health projects including a free clinic, Youth Emergency Service, and the Big Brothers Organization.

Fibromuscular Dysplasia of the Renal Arteries and Coarctation of the Aorta

Report in a Family

RONALD OLIN, M.D.* and CLIF S. HAMILTON, JR., M.D.*

ABOUT FIVE TO TEN PERCENT of hypertension cases are secondary in etiology. We have recently had the opportunity of seeing a mother and son both with secondary hypertension. The mother had fibromuscular dysplasia of the renal arteries and the son, coarctation of the aorta. Both had their hypertension relieved surgically.

We have been unable to find any similar reports of this combination in a family and whether the two conditions are related is unknown. This report presents these two cases and comments briefly on family history, histopathologic similarities and mechanisms of hypertension.

Case Reports

Case 1

A 35-year-old Caucasian housewife was first seen in January, 1971, with hypertension of four years' duration which was never adequately controlled with medication. Her mother was known to have hypertension and taking medication. Symptoms included morning occipital headaches and fatigue. On examination, the blood pressure averaged 190/116; there was a group 2 fundus, an aorticjection murmur, and bilateral, high-pitched continuous bruits in both upper quadrants of the abdomen. A renal arteriogram (Figure 1) showed bilateral fibromuscular dysplasia. There was a "string of beads" measuring 4 to 5 cms. in length in the right mid main renal artery. On the left, there was a localized 1.5 to 2 cms. area of constriction just beyond the bifurcation. Renal vein catheterizations for differential renin assays revealed 900 ng.% angiotensin from the right side, 500 ng.% angiotensin from the left side and 450 ng.% angiotensin from the inferior vena cava. Accordingly, an aortograft renal artery bypass vein graft was performed. Follow-up examinations have shown that she has remained normotensive without medication from the time of surgery to the last follow-up on July 20, 1972, when the blood pressure was 134/88.

Case 2

Her 10-year-old son was seen in March, 1972, with the history of abdominal pain when running hard. Ex-

amination revealed a blood pressure in the left arm of 162/74 and in the right arm 158/64. Other findings included visible pulsations and bruits over the scapulae, a loud precordial systolic murmur and no palpable pulses in the abdominal aorta, femoral, popliteal or

Fig. 1—Renal arteriogram of the mother showing bilateral fibromuscular dysplasia.

See editorial, page 967.

pedal arteries. Blood pressure was unobtainable in the legs. An aortogram (Figure 2) showed a coarctation of the thoracic aorta 2 cm. beyond the origin of the dilated left subclavian artery. There was collateral flow from the intercostals and internal mammary arteries bilaterally. At least two aortic valve leaflets were noted but there was uncertainty about the third. Surgery was performed with resection of the coarctation and an end-to-end anastomosis of the aorta. The pathologic specimen consisted of the area of coarctation 1 cm. in length. The 5 mm. in diameter lumen narrowed to 2 mm. in diameter in its mid portion. On microscopic examination there was typical hypertrophy and infolding of the aortic media. Postoperatively, there were good pulsations in the abdominal aorta and arteries of the lower extremities. On dismissal, the blood pressure was 126/70.

Discussion

Coarctation of the Aorta

This accounts for much less than 1% of all hypertension cases. It is twice as common in males than females and results from an abnormal obliteration of the aorta during regression of the multiple aortic arch system of the embryo. There does not appear to be any familial tendency. Classification is based largely on the site of coarctation in relation to the ductus arteriosus (preductal and postductal) and upon the age of death (infantile and adult). The adult, postductal type consists of an area of localized stricture on the superior, anterior and posterior aspects of the thoracic aorta beyond the origin of the left subclavian artery.

Longitudinal sections through the zone of coarctation reveal that the basic cause of the stricture is a curtain-like infolding of the aortic media.¹ This thickening projects into the lumen, making it narrow and eccentric. It is composed largely of collagen laid down in concentric layers with varying amounts of elastic tissue in the deeper portions. With time, there is also a secondary intimal thickening over the curtain of hypertrophied media.

There are two theories concerning the mechanism of the hypertension in coarctation of the aorta: (1) A mechanical origin in which the resistance of the coarctation is the important factor and (2) a renal basis in which a "renal vasopressor system" is activated in a manner similar to the hypertension of renal artery stenosis. Although earlier studies indicated a decreased blood flow to the kidneys in patients with coarctation of the aorta, recent studies have shown no significant hemodynamic abnormality.² Habib and Nanson³ in a series of experiments using dogs

transplanted both kidneys into the neck and noted the effect on the blood pressure before and after resection of the coarctation. Their results indicated that both mechanical and renal causes were operative at the same time to account for the hypertension. Amsterdam and coworkers⁴ measured peripheral plasma renin activity in 16 children, aged two to 13 years, with coarctation of the aorta and in controls and found no significant difference between the two groups. Seven patients with coarctation of the aorta had angiotensin infusion tests which were all negative. Their findings suggested that the hypertension of coarctation of the aorta was not associated with activation of the renin-angiotensin system although it might still be renal in origin. It was also possible that the kidney renin secretion was elevated to a degree that produced hypertension but could not be detected in the peripheral blood.

Renovascular Hypertension

This accounts for five to 25 percent of hypertension cases. It is primarily due to atheromatous disease or fibromuscular dysplasia. Fibromuscular dysplasia with secondary hypertension can occur in childhood⁵ but is more commonly seen in females between the ages of 20 and 45 years. Patients with fibromuscular dysplasia have a family history of hypertension significantly less often than patients with essential hypertension (45% compared to 70%).⁶ Familial factors in renovascular hypertension have not been further defined but Hunt⁷ has informed us that he has seen several patients with hypertension secondary to fibromuscular dysplasia of the renal arteries who have close relatives with hypertension secondary to atheromatous disease of the renal arteries. He has also seen a pair of female siblings with renovascular hypertension secondary to fibromuscular dysplasia, both of whom had their hypertension relieved surgically.

Fibromuscular dysplasia of the renal arteries includes three types of dysplastic lesions:⁸ (1) intimal fibroplasia, (2) medial fibromuscular dysplasia; four types, of which medial fibroplasia with mural aneurysms accounts for 60 to 70 percent of all dysplastic lesions; these medial lesions may be focal, multifocal or tubular stenoses with or without aneurysms and (3) adventitial or perivascular fibroplasia. Medial fibroplasia with mural aneurysms produces the typical "string of

heads" arteriogram as demonstrated in the right renal artery of the mother. Longitudinal sections through this lesion reveal multifocal stenoses due to thickened fibrous ridges alternating with areas of marked mural thinning (aneurysms). In the ridges, the arterial muscle is partly or completely replaced by fibroplasia with loose collagen replacing zones of degenerated elastic fibers within the media.

Whether these three types of dysplastic lesions are interrelated through changes from one form to another is unknown. Moreover, the exact cause of these lesions is unknown. It is theorized that they are probably congenital in origin⁹ or from traction injury to the media.

Of interest is that in 1 to 2 percent of cases of fibromuscular dysplasia of the renal arteries, similar lesions occur in other muscular branches of the aorta, commonly the cerebral arteries. In addition, the counterpart of intimal fibroplasia may be responsible for pulseless disease of the brain and upper extremities. However, the beaded arteriogram typical of medial fibroplasia with mural aneurysms has not been demonstrated radiographically or pathologically in cases of coarctation of the aorta. Certainly the focal area of

fibromuscular dysplasia in the left renal artery of the mother resembles radiographically the coarctation of the aorta in the son.

The mechanism of the hypertension in renal artery stenoses appears to be vasoconstriction and sodium and water retention effected by the renin-angiotensin-aldosterone system.¹⁰ A significant proportion of patients with renovascular hypertension have increased renin production as evidenced by renal vein and peripheral plasma activity and refractoriness to the pressor response of angiotensin-infusion tests.

Summary

Case reports of secondary hypertension in a mother and son due to fibromuscular dysplasia of the renal arteries and coarctation of the aorta, respectively, are presented. Whether the two conditions are related is unknown. Both conditions are similar in being congenital in origin, histopathologic abnormalities of the arterial media and having a renal mechanism causing the hypertension. The renin-angiotensin-aldosterone system is activated in the hypertension of renal artery stenosis whereas it does not appear to be associated with the hypertension of coarctation of the aorta.

Concurrent Lymphocytic Lymphoma and Infectious Mononucleosis

RAYMOND B. WEISS, M.D.* and B. J. KENNEDY, M.D.†

INFECTIONOUS MONONUCLEOSIS is a self-limited disease characterized by fever, sore throat, lymphadenopathy, and splenomegaly. In clinically atypical cases, diagnostic confusion between infectious mononucleosis and malignant lymphoma can occur, especially if the serological findings are equivocal.^{1,2} Patients with acute leukemia and concurrent infectious mononucleosis^{3,4,5} and patients with Hodgkin's disease and concurrent infectious mononucleosis^{6,7} have been reported. In our clinic a patient with lymphocytic lymphoma developed concurrent infectious mononucleosis, the latter disease causing temporary confusion regarding the clinical manifestations of the former.

Case Report

A 26-year-old man was well until 1959 when at the age of 13 noted an enlarged right anterior cervical node. There were no systemic symptoms of lymphoma. Biopsy of the node revealed replacement of the normal node architecture by sheets of well-differentiated lymphocytes. On current review of this biopsy slide a diagnosis of diffuse, well-differentiated lymphocytic lymphoma was made. He was treated with 2400 r to the right cervical and supraclavicular areas.

In 1961 he again developed right anterior cervical lymphadenopathy, but a second biopsy revealed only benign hyperplasia. Current review of the slide confirmed this diagnosis.

In 1962 lymphadenopathy occurred in the left anterior cervical chain. Biopsy of that node was interpreted as Hodgkin's disease. Current review of the tissue confirms the same lymphoma pathology as in 1959. He was administered an unknown dose of radiation to the left cervical area.

Three years later the patient was examined at the University of Minnesota Hospitals and was noted to have two mildly enlarged right cervical nodes, a left anterior cervical node, and a palpable spleen tip. A chest X-ray showed enlarged right hilar and paratracheal nodes. No treatment was administered and follow-up during the

next two years revealed no change in the adenopathy or splenomegaly.

In 1967 he was noted to have an enlarging spleen and new node masses in the groin, but no systemic symptoms. He was given a four-day course of nitrogen mustard, 0.1 mg per kg per day, and the inguinal node disappeared. For the next two years he remained well but continued to have mild splenomegaly. Chest X-rays were normal and showed no hilar adenopathy.

In 1969 the patient had abdominal pain and diarrhea. Gastrointestinal X-rays were normal, but a lymphangiogram showed several abnormal iliac nodes. 2500 r was administered to the periaortic nodes.

About six months later two right axillary nodes became enlarged; the spleen was not palpable. Again there were no constitutional symptoms and no treatment was given. A year later in 1971 the right axillary nodes were still enlarged and the spleen became palpable again.

In March 1972 three firm right axillary nodes, the spleen, and a vague right abdomino-inguinal mass were palpable. The lymphoma was considered to be slow progressing, but no therapy was given.

Two months later the patient had the onset of spiking fever, chills, sweats, anorexia, general malaise, and painful enlarged inguinal nodes. A three day episode of sore throat had occurred several weeks before the onset of the fever. There was no known exposure to an infectious disease. On physical examination three right axillary nodes (the largest being 3 x 4 cm) and two cm right inguinal nodes were palpable. The spleen tip was 5 cm below the costal margin. The temperature varied from 99.6 to 102° F.

A chest X-ray and intravenous pyelogram were negative. A bone marrow aspiration and biopsy and heterophile agglutination test were done. The white blood count was 7,400 with 53% neutrophils and 39% lymphocytes. The patient was regarded as having recurrent lymphoma, and he was begun on combination chemotherapy.

TABLE
Results of the heterophile antibody titers determined at intervals beginning two weeks after the onset of constitutional symptoms in May, 1972

Reprint requests to Dr. B. J. Kennedy.

Five days later the heterophile test was reported as positive in a 1:320 titer with differential absorption confirming infectious mononucleosis (Table). Study of the marrow and peripheral blood showed numerous Downey cells, types I, II, and III. The drugs were immediately stopped. There was no further fever, and the splenomegaly had disappeared. The inguinal nodes had decreased in size, but remained palpable while the enlarged axillary nodes were unchanged. Over five weeks the heterophile test reverted to zero (Table).

It was apparent that the patient's symptoms were probably the result of a concurrent episode of infectious mononucleosis, and it was considered necessary to verify the presence of lymphoma. Axillary node biopsy revealed the same lymphoma process as previously. The inguinal nodes showed only benign hyperplasia. Ten months after the onset of infectious mononucleosis, the patient feels entirely well and is not receiving any therapy.

Discussion

This patient had three lymph node biopsies which confirmed the presence of diffuse, well-differentiated lymphocytic lymphoma. The presence of fever, lymphadenopathy, splenomegaly, and Downey cells in the blood with a high heterophile titer which on differential absorption confirmed infectious mononucleosis were conclusive evidence that this patient's illness was infectious mononucleosis. There is no question that the patient had two diseases and that he did not have false serological evidence of infectious mononucleosis as has previously been reported to occasionally occur with lymphoma.¹

In patients with fever, lymphadenopathy, splenomegaly, and equivocal serological findings, confusion has existed as to whether lymphoma or infectious mononucleosis is the proper diagnosis.^{1,2} Only clinical follow-up and precise pathologic interpretation have elicited the true diagnosis.

Although well-documented cases have been reported of concurrent leukemia and infectious mononucleosis and concurrent Hodgkin's disease and infectious mononucleosis, no previous reports were found of definite concurrent lymphocytic lymphoma and infectious mononucleosis. Price and Davis⁸ reported a patient who had well-documented lymphosarcoma with a positive Paul-Bunnell test. Clinically it was at first suspected

that the patient had infectious mononucleosis, but she very soon died and was found at autopsy to have a widespread lymphosarcoma. The authors felt that the patient had only lymphosarcoma with a positive Paul-Bunnell test, and not two concurrent diseases.

Soots⁹ patient had a clinical illness suggestive of infectious mononucleosis with a positive Paul-Bunnell test and eight weeks later was proven by node biopsy to have lymphosarcoma. It is difficult to determine whether this case represented two concurrent diseases or just lymphosarcoma with a positive Paul-Bunnell test.

It has been established that the Epstein-Barr (E-B) virus is related to, and probably the cause of, infectious mononucleosis as patients with infectious mononucleosis regularly develop antibodies to the E-B virus which persist for many years.¹⁰ The E-B virus has also been implicated in the etiology of Burkitt's lymphoma,¹¹ but currently definite proof is lacking.

Elevated antibody titers to E-B virus have been found by Levine et al. in Hodgkin's disease when compared to normal controls.¹² Cells indistinguishable from the Reed-Sternberg cell of Hodgkin's disease have been described in patients with clinically-proven infectious mononucleosis,^{13,14} and Hodgkin's disease patients have been reported with a precedent history of infectious mononucleosis.¹⁵ On the basis of this evidence and the elevated E-B virus antibody titers, it has been suggested¹² that the E-B virus may play some role in the etiology of Hodgkin's disease. No such role of E-B virus in the etiology of non-Hodgkin's lymphoma has been suggested, however. It is thus considered that the concurrence of these two diseases in our patient is probably coincidental, especially since it seems to be such a rare occurrence.

This patient's clinical illness was indistinguishable from relapse of his well-documented and long-standing lymphoma. Since combination cytotoxic chemotherapy is not the treatment of choice for infectious mononucleosis, it behooves one to rule out the concurrent presence of this disease when apparent reactivation of a previously-diagnosed lymphoma occurs.

References 1-15 will be found on page 960.

What are you doing with your Alcoholic Patient?

IF YOU ARE like most Physicians, you are not doing much! Traditionally we sew up his cut, cast his fracture, give him tranquilizers and send him away.

This traditional non "treatment" of the disease, but rather treatment of the symptoms of alcoholism stems from a number of factors:

1. The average doctor receives less than two hours training in four years of Medical School on the Number Three Illness.
2. Doctors are not exposed to successful treatment programs.
3. Doctors do not accept the disease concept of this illness.

Alcoholism is a treatable illness.

Alcoholism is a disease with physical, psychologic and social components as defined by the AMA, WHO and other medical groups. Emphasis has changed from punishment to treatment.

Insurance companies have accepted alcoholism as a disease. Most alcoholics are admitted to Hospitals under diagnosis other than Alcoholism and the true problem is not treated.

In Minnesota there are now many private and public treatment programs located in Private and State Hospitals.

Treatment programs provide for detoxification, counseling, group therapy, family counseling, psychologic testing and lectures. Follow-up care is emphasized using hospital and AA programs.

Physicians who are not interested in treating Alcoholics, should get the patient into the hands of someone who is. A list of treatment centers is given. Physicians interested in treatment are often gratified. Patients are frequently bright interesting individuals who have lost control of their lives to Alcohol. Interest in the patient by the physician is quickly perceived.

Doctors must treat or refer alcoholics if we are to make progress on this epidemic illness. There are at least 75,000 undiagnosed, seriously ill, untreated alcoholics in Minnesota. Would we allow this situation to exist with any other disease?

Without equal

Without the CIBA COLLECTION OF MEDICAL ILLUSTRATIONS your reference library is incomplete

Because the CIBA COLLECTION contains 1,584 definitive illustrations by Frank H. Netter, M.D.

Because the CIBA COLLECTION systematically portrays human anatomy, pathophysiology, and clinical medicine

Because the CIBA COLLECTION utilizes a highly visual approach to make complex subjects easily understood and readily committed to memory

Isn't it time you completed your reference library?

Order your set of the CIBA COLLECTION now and we'll show you another side of Dr. Netter's art.

To commemorate the 25th anniversary of the COLLECTION's publication, we'll send you, free, four full-color, 18x24-inch, suitable-for-framing reproductions of nonmedical Netter paintings.

The irritations of man's day are often reflected in his gut.

The causes of irritable colon and the diarrheal symptoms that often accompany it can be as diverse as the systemic and emotional irritations man is faced with daily.

Although the mucoid nature of stools and the occurrence of diarrheal episodes coincident with times of emotional stress may be valuable clues to the functional nature of the disorder, irritable colon must often be diagnosed by exclusion. Such diagnostic exploration takes time. Discovery of the nature of any emotional problems may take more. During that time, Lomotil® is an ideal agent for controlling diarrheal symptoms.

Lomotil tablets are small, easy to carry and easy to take. They act promptly and effectively. Secondary effects are relatively infrequent and, once the first force of the diarrhea is controlled, maintenance is frequently effective on as little as one fourth of the initial dosage.

These same characteristics make Lomotil useful in controlling the diarrhea associated with gastroenteritis, antibiotic therapy and acute infections.

IMPORTANT INFORMATION: This is a Schedule V substance by Federal law; diphenoxylate HCl is chemically related to meperidine. In case of overdosage or individual hypersensitivity, reactions similar to those after meperidine or morphine overdosage may occur; treatment is similar to that for meperidine or morphine intoxication (prolonged and careful monitoring). Respiratory depression may recur in spite of an initial response to Nalline® (nalorphine HCl) or may be evidenced as late as 30 hours after ingestion. LOMOTIL IS NOT AN INNOCUOUS DRUG AND DOSAGE RECOMMENDATIONS SHOULD BE STRICTLY ADHERED TO, ESPECIALLY IN CHILDREN. THIS MEDICATION SHOULD BE KEPT OUT OF REACH OF CHILDREN.

Indications: Lomotil is effective as adjunctive therapy in the management of diarrhea.

Contraindications: In children less than 2 years, due to the decreased safety margin in younger age groups, and in patients who are jaundiced or hypersensitive to diphenoxylate HCl or atropine.

Warnings: Use with caution in young children, because of variable response, and with extreme caution in patients with cirrhosis and other advanced hepatic disease or abnormal liver function tests, because of possible hepatic coma. Diphenoxylate HCl may potentiate the action of barbiturates, tranquilizers and alcohol. In theory, the concurrent use with monoamine oxidase inhibitors could precipitate hypertensive crisis.

Usage in pregnancy: Weigh the potential benefits against possible risks before using during pregnancy, lactation or in women of childbearing age. Diphenoxylate HCl and atropine are secreted in the breast milk of nursing mothers.

Precautions: Addiction (dependency) to diphenoxylate HCl is theoretically possible at high dosage. Do not exceed recommended dosages. Administer with caution to patients receiving addicting drugs or known to be addiction prone or having a history of drug abuse. The subtherapeutic amount of atropine is added to discourage deliberate overdosage; strictly observe contraindications, warnings and precautions for atropine; use with caution in children since signs of atropinism may occur even with the recommended dosage.

Adverse reactions: Atropine effects include dryness of skin and mucous membranes, flushing and urinary retention. Other side effects with Lomotil include nausea, sedation, vomiting, swelling of the gums, abdominal discomfort, respiratory depression, numbness of the extremities, headache, dizziness, depression, malaise, drowsiness, coma, lethargy, anorexia, restlessness, euphoria, pruritus, angioneurotic edema, giant urticaria and paralytic ileus.

Dosage and administration: Lomotil is contraindicated in children less than 2 years old. Use only Lomotil liquid for children 2 to 12 years old. For ages 2 to 5 years, 4 ml. (2 mg.) t.i.d.; 5 to 8 years, 4 ml. (2 mg.) q.i.d.; 8 to 12 years, 4 ml. (2 mg.) 5 times daily; adults, two tablets (5 mg.) t.i.d. to two tablets (5 mg.) q.i.d. or two regular teaspoonfuls (10 ml., 5 mg.) q.i.d. Maintenance dosage may be as low as one fourth of the initial dosage. Make downward dosage adjustment as soon as initial symptoms are controlled.

Overdosage: Keep the medication out of the reach of children since accidental overdosage may cause severe, even fatal, respiratory depression. Signs of overdosage include flushing, lethargy or coma, hypotonic reflexes, nystagmus, pinpoint pupils, tachycardia and respiratory depression which may occur 12 to 30 hours after overdose. Evacuate stomach by lavage, establish a patent airway and, when necessary, assist respiration mechanically. Use a narcotic antagonist in severe respiratory depression. Observation should extend over at least 48 hours.

Dosage forms: Tablets, 2.5 mg. of diphenoxylate HCl with 0.025 mg. of atropine sulfate. Liquid, 2.5 mg. of diphenoxylate HCl and 0.025 mg. of atropine sulfate per 5 ml. A plastic dropper calibrated in increments of ½ ml. (total capacity, 2 ml.) accompanies each 2-oz. bottle of Lomotil liquid.

Makes care of the gut issue in irritable colon

Integument!

Our skin—the human integument—covers us, defines us, protects us. But skin is subject to cuts, burns, abrasions. And infections. Neosporin Ointment fights infection by providing broad antibacterial action against susceptible skin invaders. It contains antibiotics that are rarely used systemically, reducing the risk of sensitization.

INDICATIONS: *Therapeutically*, used as an adjunct to appropriate systemic therapy for topical infections, primary or secondary, due to susceptible organisms, as in: • infected burns, skin grafts, surgical incisions, otitis externa

- primary pyodermas (impetigo, ecthyma, sycosis vulgaris, paronychia)
- secondarily infected dermatoses (eczema, herpes, and seborrheic dermatitis)
- traumatic lesions, inflamed or suppurating as a result of bacterial infection.

Prophylactically, the ointment may be used to prevent bacterial contamination in burns, skin grafts, incisions, and other clean lesions. For abrasions, minor cuts and wounds accidentally incurred, its use may prevent the development of infection and permit wound healing.

CONTRAINDICATIONS: Not for use in the external ear canal if the eardrum is perforated. This product is contraindicated in those individuals who have shown hypersensitivity to any of the components.

PRECAUTION: As with other antibiotic preparations, prolonged use may result in overgrowth of nonsusceptible organisms and/or fungi. Appropriate measures should be taken if this occurs. Articles in the current medical literature indicate an increase in the prevalence of persons allergic to neomycin. The possibility of such a reaction should be borne in mind.

Complete literature available on request from Professional Services Dept. PML.

NEOSPORIN[®] Ointment

(POLYMYXIN B-BACITRACIN-NEOMYCIN)

Each gram contains: Aerosporin[®] brand Polymyxin B Salt, 5,000 units; zinc bacitracin 400 units; neomycin sulfate, mg (equivalent to 3.5 mg. neomycin base); special white petrolatum q.s. In tubes of 1 oz. and ½ oz. and ¼ oz. (approx.) foil packages.

Heredity vs. Environment

THE FREQUENTLY asked question, "Which is more important, heredity or environment?" has no clear answer. In genetically determined diseases both are important and only for individual patients can one make a distinction of relative importance. In general, it may be more precise to say heredity proposes, environment disposes.

The case report by Drs. Fisch and Chang* is a good example of this interaction. Heredity for a child with phenylketonuria proposes that a child will become abnormal if it is raised as a normal child. Drs. Fisch and Chang by suitably altering the environment dispose of this proposition and permit the child with abnormal phenylalanine metabolism to grow as a normal child.

The choices seem to be clear, at least for this hereditary disease: an abnormal gene in a normal environment can produce a child with a disease. On the other hand, the same abnormal gene in a suitably abnormal environment can produce a child without disease. Two matched negatives can make a positive.

One of the most important changes in the practice of medicine is the emerging predominance of genetic diseases. Some have estimated that 70-80% of patients admitted to hospitals within the next ten years will be admitted for complications or chronic disease associated with an inherited genetic disorder. If this is true, then the general option, outlined so beautifully for this specific

disease with this specific patient, is that the abnormal genes must be identified early in life and suitable environmental alterations be made so that the abnormal action of the gene will not lead to an abnormal child.

The work which leads to the demonstration case is slow and tedious requiring long years of dedicated effort and careful clinical and laboratory documentation as well as a long view. This is the type of medicine which few doctors have learned and which few doctors have the courage to continue once they have learned the demands of such a practice. It is the type of medicine that a person must practice for years to obtain a small measure of personal satisfaction. Nevertheless, this type of care and prophylactic treatment program must eventually be made available for other abnormal genes. Drs. Fisch and Chang illustrate the progress being made concerning phenylketonuria. Comparable studies must be done on all the amino-acidemias which can produce syndromes of mental retardation. Comparable work must be done for all types of abnormal genes which produce clinical diseases. Such prophylactic therapy producing a normal child will be many-fold less expensive than the treatments required when an abnormal gene functions in a normal environment to produce a diseased patient. This concept and the care of chronic disease must become major elements in the teaching of the medical student today and in the continuing education and re-education of physicians in practice.

Alcohol Treatment Centers*

THE AVAILABILITY of a chemical dependency treatment center within a community hospital complex tends to stimulate a wide range of involvement in the treatment of the patient. The geographical convenience permits the inclusion of the family, all concerned persons including the employer, other health care services where applicable. The opportunity is accordingly presented for expansion of post-treatment service planning and coordination with other resources, already ongoing.

The emphasis on family involvement by the author is well stated and is basic to a viable program of comfortable abstinence. The role of the physician is unique in the team approach in management of the many physical and physiological complications. His role in the intervention with the dependency is often relatively ineffective, because of the voluntary patient-doctor relationship. He is frequently unable to penetrate the fantastic denials, defenses and rationalizations of this syndrome. In reality, one sees in the majority of patients present-

ing for treatment the element of compulsion of taining from action by the employer, the court or concerned person with compelling influence.

The physician's supportive role in long-range planning once rehabilitation is underway may be vital to maintenance, ideally by the family physician, as recommended by the author. An occasional encounter with resentment from the Alcoholics Anonymous community is not without some validity. Following regain of control and rehabilitation, they recall past medical experience during which prolonged and injudicious use of chemicals led to substitution dependency, only to compound the problem. We have long been reminded by our own colleagues that the medical profession has been slow in considering alcoholism as an illness.

Increasing popularity of vigorous "post-treatment" programming by the professionals may be effective in the "treatment center failure" described by the author.

Carotid Cavernous Fistula

DOCTOR SELJESKOG* has presented a concise summary of the history, anatomy, symptomatology and management of carotid cavernous fistula. His conclusion regarding the optimum form of management coincides with this reviewer's experience. It is of utmost importance that the ophthalmic artery be occluded at the same time the intracranial and extracranial internal carotid arteries are occluded. This promotes a prompt

thrombosis in the internal carotid artery which may not occur if the ophthalmic artery is left patent. In such instances not infrequently when the ophthalmic artery is occluded at a second sitting the fistula continues to drain through collateral channels which have built up from the small dural vessels arising from the internal carotid artery in the cavernous sinus.

Philosophical Musings of a Surgeon

We cannot condone violence under the image of a good cause.

Carl O. Rice, M.D.
Editor Emeritus

Renal Hypertension

THE DESCRIPTION by Olin and Hamilton* of two cases of secondary hypertension in a family elucidates various interesting and important points. First, it emphasizes the great role of angiography in the evaluation of hypertensive patients. If no contraindication to a possibly forthcoming operation exists, every patient with hypertension should undergo angiography, because if no surgically curable cause for the elevation of his blood pressure is found, the drug therapy must be a lifelong treatment.

Secondly, the finding of a renal artery stenosis in itself does not prove its hemodynamic significance. This can only be assessed by split renal function tests or by measurement of the pressor activity of renal venous blood. The latter is cur-

rently most often done by radioimmunoassay, where the formation of angiotensin, induced by renin, is measured with the help of isotopes. If the test does not give a high enough ratio to indicate the site of increased renin formation, pharmacological¹ or positional² stimuli, which have more affect on the kidney behind a significant stenosis, may be applied.

Third, it is not likely that the hypertension of patients with coarctation of the aorta is due to the same principle as in those with renovascular hypertension, which involves the renin-angiotensin-aldosterone system, but it still could be renal in origin.³ The authors' discussion of a possible common denominator in these patients' vascular morphology is certainly intriguing.

Claus A. Pierach, M.D.
Minneapolis, Minnesota

Transfusion Therapy with CPD

THE HISTORY OF transfusion therapy is, in part, the study of methods to preserve blood outside of the body. Many physicians are familiar with direct transfusions and the evolution of preservation methods since then—citrate solutions, Alsever's solution, heparin, dextrose solutions (ACD), frozen blood, and now CPD* solution. The addition of dextrose, to preserve the living red cell, and particularly its diphosphoglycerate and adenosine triphosphate metabolism, has been the major advance in this period. All blood used in Minnesota is now preserved in CPD solution which results in slightly better cell preservation and is more physiological when transfused, as discussed by Dr. McCullough and B. Weiblin† in his issue.

The patient who receives massive transfusions of CPD preserved red cells suffers less physiological insult and the cells function slightly better and longer in the recipient. The clinician should know his order for transfusion will now result in a slightly different response. The improvements are not spectacular, but blood service is a \$500,-million 'industry' involving six million donors, and improvement of any magnitude is important, both to the individual and to society.

In a way, even moderate improvements in transfusion therapy aggravate a problem—heavy utilization, perhaps overutilization, of a scarce and precious biological commodity.

Coronary Artery Disease

THE IDENTIFICATION of the patient at high risk with coronary artery disease has been and continues to be a major difficulty in clinical medicine today. Prospective studies such as those at Framingham and retrospective statistical analysis in the Rochester study¹⁻⁴ have pointed out the predictive value of risk factors and have substantiated the use of certain clinical findings in determining a prognostic index. Cardiac enlargement, significant hypertension, cigarette smoking, electrocardiographic scars and conduction disturbances, elevated cholesterol, and congestive heart failure have been shown to correlate with a high mortality¹⁻⁴.

In his article "Clinical and Invasive Studies of Coronary Artery Disease" Peterson* has re-evaluated the use of clinical classification into functional classes on a basis of angina pectoris in determining the high risk patient with coronary disease. He points out that mortality rises as the class increases II to IV correlating well with the degree of anginal distress. This observation is in agreement with what others have found, however, Bruscheke, et al. (and others^{5,6}) have pointed out the value of coronary arteriography and IV angiography in understanding these prognostic signs. They have shown that clinical classification into functional classes on the basis of angina pectoris loses its predictive value in arteriograph-

ically comparable cases. The duration of angina pectoris has some predictive value, but of limited degree. The other major underlying factors are of more specific prognostic value, namely, the number of vessels involved, left ventricular dysfunction, electrocardiographic abnormalities, heart size, etc. We must be very careful in assuming that functional class alone is of major predictive value. The lack of randomization and criteria used in the selection of those for invasive studies in the paper by Doctor Peterson, makes it difficult to arrive at any definite conclusion.

Utilizing the known high risk factors, it is possible to construct a risk profile for mortality in five years and or recurrent myocardial infarction in the same period. The advantage that this has over a functional classification based on anginal disability is that it would allow identification of the patient at high risk with coronary artery disease who may be functional class I to II at the time the patient is seen. This approach would be more comprehensive and would allow selection of the patient at high risk with angina for early invasive, diagnostic, and therapeutic efforts before he becomes functional class III or IV. I, for one, hope that we see such an approach develop in the very near future for the selection of patients for more invasive studies.

"Third World" Health

ELSEWHERE IN THIS ISSUE of MINNESOTA MEDICINE, Dr. James Fett* of Pierre, S.D. has set forth, in stark terms, some of the health problems faced by the developing nations of the world. Dr. Fett reports on the basis of extensive first-hand knowledge, for he has served as a missionary physician in Africa for several years. I have been privileged to visit, for short periods, rural health care facilities in a South American country, two African countries, and South Vietnam, and I can testify to the reality of what Dr. Fett has reported.

Two points stand out as I reflect on my own limited experiences with "third world" health problems and as I read Dr. Fett's article. The first is that the developing countries are now fighting the medical battles that our nation was fighting at the turn of the century. The various indigenous infectious diseases still constitute the major health problems. Public Health measures, including population control, are the crying needs. Safe water supplies are more important for these countries right now than open heart surgery, a concept that our medical educators do not always grasp as they set out to be of help to these nations.

The second thing that has impressed me is the importance of the role played by various non-M.D. health personnel in these countries, individuals that we would probably refer to as "physician's assistants" in our country. Countries with one physician to 10,000 population currently have little or no prospect of reaching what we would consider a reasonable physician-to-population ratio within this century. Of necessity they must make do with less-well-trained personnel. I have been favorably impressed with how well this apparently works in many instances. I have, for example, seen in South Vietnam a district health facility ministering to the health needs of several thousand people under the direction of a very capable physician's assistant, who had had the equivalent of about two years of post-high-school training in health care.

Dr. Fett has done us a service in reminding us that health care problems are universal. I would only add that all of us American physicians could profit from a period of service in a "third world" mission, for surely it would do us good to be reminded of our own not so distant past and to appreciate anew the strides that medicine has made in our own country.

Cover Photo

"I'm Not Here"

Dr. Earl C. Henrikson took the cover photo in the woods of Wisconsin. The fawn was lying motionless amongst the leaves and its speckled fur is its camouflage. Dr. Henrikson was able to get many shots as he quietly walked up to it using a Contarex camera with a 135 mm lens.

Wild life photography using still and movie cameras is his hobby, and annually he shows films at the Audubon Society, Minneapolis Bird Club Show at the Public Library and before other groups.

Dr. Henrikson's specialty is general surgery. He is Associate Professor Emeritus in the Department of Surgery at the University of Minnesota, Minneapolis.

Carcinoembryonic Antigen

CARCINOEMBRYONIC ANTIGEN (CEA)* is a misnomer. CEA is a glycoprotein complex of antigens obtained by perchloric acid extraction of embryonic colon, meconium, or colon cancer tissue. CEA may be further partially purified by molecular weight, configuration, and electrical charge. CEA has not been characterized as to exact molecular weight or amino acid composition. CEA has not been isolated as a single molecular complex. CEA has not been synthesized.

CEA was injected into animals by Gold and Freedman in order to develop antibodies. These antibodies were subsequently used to test the serum of patients for the presence of circulating CEA. To date, there have been conflicting reports regarding the usefulness of CEA as a tool in diagnosis, prognosis, or treatment of cancer patients.

Anti-CEA antibodies are not made against a single antigen but rather against a complex of antigens. Thus, it is readily apparent that CEA tests will yield varied results in any large series. Radioimmunoassay is a highly sensitive and complex technical tool. The results of radioimmunoassay serum tests when applied to CEA are at present difficult to corroborate in any two laboratories. An eight to 10% error has been reported between two laboratories using the same tech-

niques and serums for testing. This variance is probably due to the fact that a single antibody and a single molecular antigen are not being used in the system.

CEA is not a tumor specific antigen. CEA is more likely a tumor associated group of antigens one of which may be specific for entodermally derived cancers. CEA is released from noncancerous injured cells of lung, kidney, gastrointestinal tract, and liver. Elevated CEA levels are also reported in smokers, patients on vitamin pills, and patients with various illnesses.

At present CEA is not of value in screening patients for cancer due to its lack of specificity and high false positive rate. CEA should be of value in following patients with cancer of the colon or pancreas for evidence of recurrence. Our own studies, done in conjunction with Dr. Henry Bates, Dr. Lyle Hay, and Dr. Lance Crombie involve several hundred patients and are to date inconclusive on this point.

The above should not detract from the major contribution of Dr. Phil Gold. He demonstrated that cancer associated antigens circulate and can be measured in the serum. This has raised our hope that truly tumor specific antigens will be isolated in the near future, allowing radioimmunoassay with monospecific antisera to detect cancer in its early stages. To this end we are all dedicated.

Letter to the Editor

Dear Editor:

Many thanks for getting rid of the staples binding in MINNESOTA MEDICINE. I used to *hate* to review and save its articles because of the inevitable struggle with those little pieces of metal. It is also pleasing to have all the references in the journal (why was it ever otherwise?) but please keep them with the articles.

Ken Williamson, M.D.
St. Cloud, Minn.

In Memoriam

HANS P. BARTHOLDT, M.D.

Dr. H. P. Bartholdt, 50, of Mora, died July 8th. He graduated in 1952 in Munich, Germany, as a physician, and two years later received a doctorate in medicine. He came to the United States in 1956, and after two more years of training, interning, he started practicing surgery and orthopedic surgery in Bismarck, North Dakota. He later moved to Mora and set up his practice.

Dr. Bartholdt was a member of the Royal Society of Health, the Minnesota State Medical Association, the American Medical Association and the East Central Minnesota Medical Society. He was also cited by the Queen of England.

Dr. Bartholdt is survived by his wife, Helga, a daughter, Sabine and one son, Ralf.

CHESTER E. THIEM, M.D.

Dr. Chester E. Thiem, Mankato internist, died July 8. He obtained his medical education at the University of Minnesota.

Dr. Thiem was a member of the Mankato Clinic, the American Medical Association, the Minnesota State Medical Association and the Blue Earth County Medical Society.

He is survived by his wife, Karin, sons, Christopher, Fred and Nick and daughter, Lisa.

HELENE LITKEWITSCH, M.D.

Dr. Helene Litkewitsch, 65, St. Paul physician, died August 24. Born and educated in Russia, Dr. Litkewitsch, however, interned at St. Luke's Hospital in St. Paul.

She was a member of the Ramsey County Medical Society and the American Medical Association and an associate Member of the Minnesota State Medical Association.

Dr. Litkewitsch is survived by her husband, Eugene, and son, George.

RAYMOND J. JACKMAN, M.D.

Olmsted County Health Officer, Dr. Raymond J. Jackman, 67, died August 10. A noted physician, he was president of the Minnesota State Medical Association in 1970-71, president of the Minnesota Health Board in the 1960s and was a former chairman of a section of the American Medical Association. He had been a senior consultant in proctology at the Mayo Clinic and a former head of the Proctology Section. Dr. Jackman authored numerous books on proctology and was a former member of the American Board of Colon and Rectal Surgery. His medical degree was obtained at the University of Iowa.

Dr. Jackman was an honorary member of the Proctological Latina (Italy), the Argentina Proctologic

Society and the Alaska State Medical Association. He was a member of the council of the American Proctologic Society and the Zumbro Valley Medical Society.

Dr. Jackman is survived by his wife, Kathleen, a daughter, Collette, and two sons, Doctors Steven Jackman and Roger Jackman.

JOHN G. RUKAVINA, M.D.

Dr. John G. Rukavina, 59, St. Paul dermatologist and former clinical associate professor of dermatology at the University of Minnesota, died September 5.

A native of Hibbing, Dr. Rukavina earned several degrees at the University of Minnesota, including his degree in medicine. In recognition of his work in the field of dermatology, Dr. Rukavina was admitted into the National Society of Sigma Xi.

He was a diplomat of the American Board of Internal Medicine and the American Board of Dermatology and a member of the Ramsey County Medical Society, the American Medical Association, the Minnesota Dermatological Society and the Minnesota State Medical Association.

Dr. Rukavina is survived by his wife, Florene, sons, John, Gregory and Phillip and one daughter, Elizabeth.

CARL W. RUMPF, M.D.

Dr. Carl W. Rumpf, 78, physician and surgeon in Faribault, died August 21. A native of Chicago, Dr. Rumpf after his family moved to Minnesota attended schools in Faribault and later attended the University of Minnesota College of Medicine.

He served as school physician for Shattuck and St. Mary's Schools in addition to his private practice. He was a member of the Rice County Medical Society, the American Medical Association, the Southern Minnesota Medical Association, the American Academy of Family Physicians and the Association of Railway Surgeons. He was a 50 Club and Life Member of the Minnesota Medical Association. In 1958, he was awarded the "Old Shads" citation for distinguished service to the community of Faribault and Shattuck.

Dr. Rumpf is survived by two nephews and a niece.

LEON J. PETIT, M.D.

Dr. Leon J. Petit, 88, Minneapolis physician, died August 12. A native of Minneapolis, Dr. Petit obtained his medical education at the University of Minnesota Medical School. He also studied in Paris and Vienna.

Dr. Petit was a member of the Hennepin County Medical Society and the American Medical Association and a 50 Club and Life Member of the Minnesota State Medical Association.

He is survived by a daughter, Mrs. Pauline Hanson, and two sons, Dr. Julian V. Petit and Jean L. Petit.

Medicine's men on the Hill.

Just who are they? They're the AMA's permanent representatives to Congress and a part of the AMA's Washington staff.

In the 92nd Congress, about 10% of all legislation introduced was health-related—more than 2,500 bills. The AMA's representatives serve as the eyes, ears and voice for our profession on such legislation. Keeping in close contact with members of Congress and their staffs. Explaining and promoting our profession's views. Reporting on legislation. And providing legislators with resource material and information on medical and health subjects.

They're on the Hill to protect your interests,

lobbying to retain the basic principles of private practice in any government health program that might be enacted. Equally important, they lobby to insure the passage of constructive and workable health legislation for the public.

Sure, the AMA lobbies. We lobby for the rights and interests of our profession and for quality medical care for every American. By adding your voice, your support, we can be even more effective.

Join us.

We can do much more together.

American Medical Association

535 N. Dearborn St./Chicago, Ill. 60610

Maybe the patient's self-diagnosis is right. He could have hay fever. But that bright red nasal mucosa, along with the thick discharge and excoriation around the nares, strongly suggests that the main problem is a cold. Hay fever or another form of allergic rhinitis may or may not be an underlying factor.

If a complete history and examination rule out allergic rhinitis, the long-term outlook will be a lot more favorable than his own "diagnosis" would have indicated.

But right now, whether he's got allergic rhinitis or a cold, he's suffering from the same irritat-

ing symptoms of drip, congestion and stuffiness. Try DIMETAPP EXTENTABS®. They're formulated to relieve these symptoms without much chance of causing drowsiness or overstimulation. Your patients will appreciate the 24-hour relief they can get from just one tablet every 12 hours.

Cold or

Allergy?

Whether it's a cold or an allergy, Dimetapp Extentabs® effectively relieve stuffiness, drip and congestion.

INDICATIONS: Dimetapp Extentabs are indicated for symptomatic relief of allergic and nonallergic rhinitis and other irritations of upper respiratory tract, such as the common cold, seasonal allergies, sinusitis, rhinitis, congestion and edema. In these cases, it relieves inflammation and excessive upper respiratory secretions, thereby affording relief from nasal stuffiness and postnasal drip.

CONTRAINDICATIONS: Hypertension, glaucoma, and other significant cardiovascular disease. Dimetapp Extentabs are contraindicated during pregnancy and lactation. Under 1 year of age. Beware of the dry mouth thickening effect on the lower respiratory secretions. Dimetapp Extentabs should be used in the treatment of bronchospasm. Also, Dimetapp Extentabs should be used with caution in patients with heart disease and in those with a history of alcoholism.

and children, particularly young children, who may produce convulsion and death.

PRECAUTIONS: Advise your patients with a diagnosed pheochromocytoma, hypertension, or hyperthyroidism that patient should be alert to the following symptoms: rapid heartbeat, nervousness, tremor, dry mouth, dizziness, etc. Patients receiving any of the above should be advised to consult their physician if they experience any of the above symptoms.

Dimetapp Extentabs®

Dimetane® (brompheniramine maleate), 12 mg.; phenylephrine HCl, 15 mg.; phenylpropanolamine HCl, 15 mg.

with alcohol, hypnotics, sedatives, tranquilizers, etc.

ADVERSE REACTIONS: Adverse reactions to Dimetapp Extentabs may include hypersensitivity reactions such as skin rash, urticaria, leukopenia, agranulocytosis, and thrombocytopenia; drowsiness, fatigue, dryness of the mucous membranes, and thirst; if too much clearing of nasal fluid is created, urinary frequency and dysuria, palpitation, dizziness, hypertension, headache, nervousness, tremor, dizziness, or visual disturbances; in drug addicts, CNS depression and decreased stimulant effect; all these may be minimized by food, constipation, and epigastric distress.

HOW SUPPLIED: Light blue Extentabs in bottles of 100 and 400.

when pain goes on... and on... and on-

For the patient with a terminal illness, PAIN past, present, and future can dominate his thoughts until it becomes almost an obsession. The more he is aware of the pain he is now experiencing, the more difficult it is to erase his memory of yesterday's pain, and to allay his fearful anticipation of tomorrow's pain.

Surely the last thing this patient needs is an analgesic containing caffeine to stimulate the senses and heighten pain awareness. A far more logical choice is Phenaphen with Codeine. The sensible formula provides $\frac{1}{4}$ grain of phenobarbital to take the nervous "edge" off, so the rest of the formula can help control the pain more effectively. Don't you agree, Doctor, that psychic distress is an important factor in most of your terminal and long-term convalescent patients?

the analgesic formula that calms instead of caffeinates

Phenaphen[®] with Codeine

Phenaphen with Codeine No. 2, 3, or 4 contains: Phenobarbital ($\frac{1}{4}$ gr.), 16.2 mg. (warning may be habit forming); Aspirin ($2\frac{1}{2}$ gr.), 162.0 mg.; Phenacetin (3 gr.), 194.0 mg.; Codeine phosphate, $\frac{1}{4}$ gr. (No. 2), $\frac{1}{2}$ gr. (No. 3) or 1 gr. (No. 4) (warning: may be habit forming).

Indications: Provides relief in severer grades of pain, on low codeine dosage, with minimal possibility of side effects. Its use frequently makes unnecessary the use of addicting narcotics. **Contraindications:** Hypersensitivity to any of the components. **Precautions:** As with all phenacetin-containing products, excessive or prolonged use should be avoided. **Side effects:** Side effects are uncommon, although nausea, constipation and drowsiness may occur. **Dosage:** Phenaphen No. 2 and No. 3—1 or 2 capsules every 3 to 4 hours as needed. Phenaphen No. 4—1 capsule every 3 to 4 hours as needed. For further details see product literature.

Ⓜ Phenaphen with Codeine is now classified in Schedule III, Controlled Substances Act of 1970. Available on written or oral prescription and may be refilled 5 times within 6 months, unless restricted by state law.

Snowmobiling with Associated Maxillofacial Injuries

CONRAD I. KARLEEN, M.D., D.D.S., F.A.C.S.*

SNOWMOBILES WERE invented for recreation and commercial ventures. However, the accident rate is rising due to carelessness and negligence in snowmobile operations. The consumption of liquor is a major factor. In a report from Ontario, Canada¹ the driver's condition was stated as "ability impaired" or "had been drinking" in 23% of the snow vehicle collisions, (62 of the total 272 accidents). In fatal collisions, in which snow vehicle driver's condition was specified, 50%, (12 out of 24 deaths) indicated alcohol was a factor. Post-mortem blood alcohol concentrations were available for six of the 12 snow vehicle drivers. In one the level was 0.13% and in five exceeded 0.17%. A study in Minnesota² indicates that one out of every 25 snowmobilers can be expected to be injured during his snowmobiling career.

In 1964 there were only 15,000 snowmobiles in the United States and Canada; as of March 1972 there were over 1,960,000 machines.³ In Minnesota 310,507 machines were registered in January 1973. The number has more than doubled since 1970. Minnesota requires all snowmobiles to be registered.

Bombardier of Valcourt, Quebec, is given the credit for being the first to develop the snowmobile into a salable product.⁴ His first commercial snow vehicle was developed in 1936, and in 1959-1960 he began the manufacture of snowmobiles. It was not until 1964 that the machine became available in mass production. Snowmobiling is the fastest growing winter sport in North America, increasing 35% yearly compared to 20% for the remainder of the recreational industries.⁵

This paper is concerned with 392 snowmobile injuries during the 1969 season from five Minne-

apolis suburban hospitals with special emphasis on maxillofacial (head and neck) trauma.

Material

Out-patient and in-patient hospital charts for 1969 were reviewed in five suburban hospitals peripheral to Minneapolis, Minnesota. These five hospitals were selected because of their high admission rates for snowmobile accidents.

Results

A total of 392 patients involved in snowmobile accidents in 1969 were treated in the five hospitals.

Of the total 392 injured, 209 received treatment for their injuries in the two smaller hospitals (Table 1). These hospitals were located near more open areas where there are greater opportunities for snowmobiling than the three hospitals located in the more congested areas.

Of the total, 103 sustained maxillofacial (head and neck) injuries (Table 2) and 20% were hospitalized.

TABLE 1
Distribution of Snowmobile Injuries by Hospitals
January 1, to December 31, 1969

Hospital	Beds	Inpts	Number of Injuries Outpts	Total

*Consultant for the Occupant Protection, Sub-Committee of the SAE Snowmobile and All-Terrain Vehicle Committee.

Presented at the Automobile Engineering Congress, January 14, 1972, Detroit, Michigan and at the Annual Meeting of the Minnesota State Medical Association May 19, 1972, Rochester, Minnesota.

Maxillofacial (head and neck) injuries accounted for 26% of all injuries in this series (Table 3).

Sixty-one percent of all head and neck injuries were lacerations of the face and scalp (Table 4). The average stay of the in-patients was three days except patients with associated injuries.

TABLE 3
Distribution of Snowmobile Injuries by Body Area
1969

Body Area	Inpts	Outpts	Total	Percent
Cranial	0	4	4	1.0
Maxillofacial (Head & Neck)	20	83	103	26.0

Total	20	83	103

* See case histories

In 25 out-patients treated, the mechanism the injury was unknown (Table 5). They were listed in the hospital charts as "snowmobile accidents" and the direct cause could not be determined. Twenty-nine injuries (26%) were caused by striking part of the vehicle, 14 of them by the windshield. Seventeen injuries (16%) were caused by striking barbed-wire or cable. One-half of these patients were hospitalized.

TABLE 5
Mechanism of Maxillofacial (Head & Neck)
Snowmobile Injuries
1969

Mechanism of Injury	Inpts	Outpts	Total
Thrown from Vehicle	3	9	12
Struck Part of Vehicle	4	25	29
Collision with Fixed Object	2	6	8
Riding behind Snowmobile	1	2	3
Ran into Barb-Wire or Cable	9	8	17
Collision while Intoxicated	1	0	1
Overturned Vehicle	0	6	6
Hit by Auto	0	1	1
Caught Scarf in Clutch	0	1	1
Mechanism of Injury Unknown	0	25	25
Totals	20	83	103

Of the total injuries 68.8% occurred after the daylight hours (Figure 1).

Thirty-four injuries (33%) occurred in males between the ages of 25 and 35 (Figure 2).

One death occurred in Minneapolis, (Hennepin County) on January 10, 1970 (Table 6). A 12-year-old girl was strangled when a long scarf was pulled into the clutch of the family snowmobile in their backyard.

TABLE 7

DEATHS FROM SNOWMOBILE INJURIES IN MINNESOTA JANUARY, 1969 THROUGH MARCH, 1972

MINNESOTA DEPARTMENT OF
NATURAL RESOURCES

WILLIAM SEVERSON, OUTDOOR SAFETY
SPECIALIST

The increase in death rates (Table 7) can be correlated with the increase in the number of operating snowmobiles. Forty-one percent of all deaths in the 1971-1972 series were caused by snowmobile-motor vehicle collisions.⁶

Case Histories

Cases 1 and 2

Husband and wife, both age 30, were riding in a field on a snowmobile about 12:30 a.m., January 1, 1969, and ran into a barbed wire fence. He sustained an avulsed flap laceration of the eyebrow and frontal area. She sustained a severe avulsed laceration involving the upper eyelid and entire periorbital area. Both patients were admitted to the hospital and plastic surgical repair was carried out under general anesthesia. Each required a hospitalization of four days. In April 1970 she had secondary scar revision of the upper eyelid.

Case 3

A white male, age 35, was snowmobiling during the middle of the night when he struck a steel wire sustaining a corneal laceration, multiple facial lacerations, fracture of the malar-zygomatic compound, fracture of the floor of the orbit, transverse fracture of the maxilla, and compound fractures of the nasal bones. He was hospitalized for 15 days. On the date of discharge the facial bones fractures had been adequately reduced and there was no diplopia. The past history revealed that he had been treated for a cervical fracture one year previously as a result of an automobile accident.

Case 4

A white male, age 33, was returning home alone on his snowmobile at 2:15 a.m. after a party December 21, 1969, when he was struck and run over by six snowmobilers. He did not lose consciousness and was on his feet after the accident. On admission to the hospital there was a distinct odor of alcohol. Examination revealed periorbital edema, subconjunctival hemorrhages, and contusions and abrasions of the face, back, and extremities. Xrays of the skull, facial bones, and extremities were negative. The patient was discharged from the hospital the next day.

Case 5

A white male, age 35, struck a steel gate while snowmobiling at 3:00 a.m. and was rendered unconscious at

TABLE 6
Causes of Death from Snowmobile Injuries
in Minnesota
January, 1969 through March, 1970

Cause of Death	Number	Age
Struck a Steel Cable (Same Accident)	2	17, 20
Drowning	1	33
Collision with Auto	2	18, 47
Hit by Train	2	30, 45
Strangulation (Scarf)	1	12
Hit Pole during Organized Race	1	19
Crushed under Snowmobile	1	44
Collision with other Snowmobile	2	25, 43
Thrown from Snowmobile	1	30

William Severson, Outdoor Safety Specialist

the time of the accident, but regained consciousness upon arrival at the hospital. He required a tracheostomy on admission. He sustained lacerations to the frontal area, fractured larynx, fracture dislocation of C₅ and C₆, fracture dislocation of T₁₀, and T₁₁, and a hemothorax. He was hospitalized for 95 days and later transferred to the Veterans Hospital as a total paraplegic.

Discussion

In view of the growing accident toll, it is necessary that legislation be enacted governing snowmobiles, a safety training program be established and continuing efforts be made to improve the safety features of the machine. In Minnesota snowmobiles are under the jurisdiction of the Department of Natural Resources and are governed under a different code than other motor vehicles.

In Minnesota one of the laws passed in 1969⁷ makes it unlawful for a person under 14 years of age to make a direct crossing of a trunk or county highway. Between 14 and 17 years of age, to cross a highway, the driver must have a snowmobile certificate. Through the program of safety training for young snowmobilers,⁸ the Department of Natural Resources expects to reach an estimated 50,000 youngsters in Minnesota in the 14-17 age group. Legislation should require training and certification of the operator of a snowmobile with standards similar to those for drivers of automobiles.

During the 1972-1973 season the Department of Natural Resources predicts that there will be 50 deaths and 12,000 accidents of which 70% of the total will be personal injuries severe enough to require medical attention.

The manufacturers of snowmobiles are aware of the fact that many safety features must be built into the machines to make them safer in operation for the drivers and occupants to prevent serious injuries. Mongé and Reuter⁹ reported that the most serious injuries were of the head and most frequent to the legs. Chism and Soule¹⁰ reported severe back injuries due to lack of good seat cushions and shock-absorbing qualities of the snowmobile.

To prevent injuries the Occupant Protection Subcommittee of the Society of Automotive Engineers Snowmobile and All-Terrain Vehicle Committee recommended several safety features which are now being built into snowmobiles by a few manufacturers. Some of these safety features are listed below:

1. A Pulley Guard and Shield to enclose the

moving parts so that disintegrated parts will not escape in the direction of the operator or passenger causing injury and loose clothing will not enter or become entangled in the moving portion. Loose clothing is always considered a potential hazard.

2. To decrease accidents due to a sticky throttle by using an ignition "kill button" on the handle next to the throttle lever.
3. Padding of the handle bars to decrease facial injuries.
4. Improvement of seat cushions and shock absorbers to reduce back injuries.
5. Improvement of foot rests, a rubber non-skid pad wide enough to provide enough room for the occupant's feet.

Forty-one percent of all injuries were of the lower extremities. Enclosure of the exposed track and gear should be incorporated into the machine to decrease leg and foot injuries.

Twenty-six percent of all the injuries were of the head and neck. Martyn¹¹ reported 13% head and neck injuries and 6% corneal injuries in 135 hospital patients in a three-year survey (1967-1969) in Peterborough, Ontario. Dominici and Drake¹² reported 20% injuries of the head and neck in 155 patients in which complete statistics of the accidents were obtainable during the 1968-1969 season in Maine. Fink and Mongé¹³ reported 31 soft tissue injuries of the head and seven fractures of the skull and facial bones in a total of 171 patients treated in hospitals in Duluth, Minnesota, from November 26, 1968 through March 18, 1969. Withington and Hall¹⁴ reported seven facial injuries (fractures, lacerations) and seven closed head injuries (concussion and skull fractures) in 59 persons involved in snowmobile-related accidents. To prevent the snowmobilers from facial injuries from barbed-wire, cables, branches, and to decrease the wind-chill factor the author recommends that the wind shield should be raised to the height of the top of the head of the seated passenger and a roll-bar to be incorporated around the windshield. Four of the deaths in the 1971-1972 series were caused by snowmobile roll-over.⁶

The wearing of goggles and helmet would help to prevent corneal injuries and cerebral concussion. Daniel and Midgley¹⁵ proposed a crash helmet incorporating an integral face mask and visor currently worn by Grand Prix racing car drivers without restriction to their vision. Visors

for day and night driving can be attached to the helmet. This may help to reduce the number of eye injuries and facial bone fractures.

Summary

The charts of 392 patients who sustained snowmobile injuries from January 1, 1969 through December 31, 1969 and received treatment in five suburban hospitals outside the city limits of Minneapolis, Minnesota were reviewed.

Of the total 392 injured, 103 patients sustained maxillofacial (head and neck) injuries and accounted for 26% of all injuries in this series. The 61 deaths in Minnesota are listed from Jan-

uary 1, 1969 through March 1972. Four case histories are presented. Improvement in the windshield construction should be one way to decrease the number of facial injuries.

Acknowledgment

The author wishes to thank Barbara G. Kennedy, R.R.L., director of Medical Record Department, Unity Hospital, Fridley, Minnesota for the statistical analysis; Kenneth M. Strom, attorney at law, Austin, Minnesota for legal counseling regarding snowmobile laws and regulations in Minnesota; and Sister Margaret Francis Schilling, Medical Photography Laboratory, St. Mary's Hospital, Minneapolis, Minnesota for the preparation of the slides and graphs.

Citrate Phosphate Dextrose (CPD) Anticoagulant

in Blood Transfusion

JEFFREY McCULLOUGH, M.D.* and BARBARA J. WEIBLEN, BA (MT) ASCP†

BLOOD STORED for transfusion, must be properly anticoagulated and well preserved. The original anticoagulant, sodium citrate, underwent several alterations to improve red cell viability, and for the last quarter century, acid-citrate-dextrose (ACD) has been the most widely used anticoagulant. Recent efforts to improve the quality of transfused blood have led to the development of citrate-phosphate-dextrose (CPD) anticoagulant.

Red cell viability is of major importance in evaluating anticoagulant solution but other factors should also be considered. During storage of blood, biochemical changes occur, which result in decreased red cell function and present a potential hazard to the recipient. Thus, the ideal anticoagulant should: (1) minimize these biochemical changes, (2) provide for good red cell survival and function and, (3) allow the harvesting of coagulation factors and platelets for use in component therapy. CPD appears to accomplish most of these functions better than ACD and is currently becoming widely utilized in blood transfusion.

Composition of CPD

The degree of cell damage during blood collection is a major factor in erythrocyte viability. ACD anticoagulant is hypotonic to red cells and the first 100 ml. of collected blood has a high percentage of hemolysis. In developing CPD anticoagulant, Gibson, et al.¹ attempted to provide a solution that is isotonic for red blood cells during all stages of collection and still produces an optimum pH in the final plasma. In CPD, the ratio of citric acid to trisodium citrate has been altered (Table 1) to give a net decrease of 15% in the citrate ion present and an increase in the pH of the solution. Both solutions contain the same amount of dextrose, which serves as a substrate for red cell glycolysis. Additional phosphate is

present in CPD to retard the breakdown of organic phosphates (ATP and 2,3-DPG) and thus provide better red cell viability and function.

TABLE 1
Comparison of the Composition of
CPD and ACD Anticoagulants

	ACD	CPD
Citric Acid	540 mg	206 mg
Sodium Citrate	1.49 g.	1.66 g.
Sodium Biphosphate	—	140 mg.
Dextrose	1.65 g.	1.61 g.
Volume Use for 450 ml of Whole Blood	67.5 ml	63 ml

Biochemical Changes in ACD and CPD Blood During Storage

The effects of this difference in anticoagulant composition can be seen by comparing the biochemical changes during storage of ACD blood and CPD blood (Table 2). The pH decreases due to the production of lactic acid by red cell glycolysis. The plasma pH of CPD on the day of collection is approximately 7.2, which is considerably higher than the pH of 7.0 in fresh ACD blood. Throughout 21 days of storage, the pH of CPD blood remains higher than that of ACD blood, making CPD blood safer for massive transfusion. Dextrose concentration has not been reported during storage of CPD blood. However, the amount of dextrose in CPD anticoagulant is the same as in ACD, so the concentration in CPD blood should be approximately the same as ACD blood. The plasma hemoglobin in CPD stored blood is less than ACD blood, probably because there is less hemolysis due to improved red cell preservation. Plasma sodium should be slightly higher in CPD than in ACD blood because of the additional sodium citrate. However, the only data available reports plasma sodium to be approximately the same in CPD as in ACD stored blood at 21 days. Plasma potassium is slightly less in CPD than ACD stored blood because of the decreased red cell hemolysis in CPD blood. Inorganic phosphate concentration is significantly higher in CPD blood because of

ne additional inorganic phosphate in the anticoagulant solution.

Due to its isotonicity, CPD causes little osmotic damage to red cells during collection, resulting in better survival. The current NIH standard for red cell preservation is the survival of 70% of the red blood cells for 24 hours after transfusion. After 21 days of storage, red blood cells stored in ACD have approximately 80% survival, while CPD red cell survival is slightly higher.² However, after 28 days of storage, the survival of ACD erythrocytes falls below 70% while the survival of CPD cells is 70-75%.^{2,3,4} Thus, CPD anticoagulant is used for red cell storage of 28 days in parts of Europe and in Canada, although it is restricted to 21 days in the United States.

For effective red cell transfusions, the cells must not only survive storage but also must carry out their function of supplying oxygen to the tissues. When oxygen is bound to hemoglobin, the enzyme 2,3-diphosphoglycerate (2,3-DPG) is required to facilitate release of oxygen to the tissues. Red cell function can be evaluated by measuring 2,3-DPG or the partial pressure of oxygen at which 50% of the hemoglobin is saturated with oxygen (P_{50}). Both 2,3-DPG and oxygen P_{50} are better maintained in CPD blood than ACD (Table 3). In this respect, CPD blood after one week of storage is comparable to fresh blood while ACD blood deteriorates rapidly during the first few days of storage.^{5,6}

Clinical Experience with CPD Blood

CPD blood has been used experimentally in a number of clinical situations. Pediatric patients

at the Boston Childrens Hospital received over 3,000 units of CPD blood with no deleterious effects or complications attributed to the use of CPD anticoagulant.⁷ Thirty-seven of these patients received blood between 21 and 28 days old and in amounts greater than their own blood volume. In cases of massive transfusion, there was less depression of blood pH with CPD blood than with ACD. One child received approximately three times his blood volume of stored CPD blood, but maintained a normal blood pH.

Because citrate binds calcium and the increased phosphorus level could lead to further depression of serum calcium, it has been suggested that multiple transfusions of CPD blood might lead to hypocalcemia. However, Gibson, et al.⁸ studied several patients who received massive transfusions of CPD blood and did not find hypocalcemia or hyperphosphatemia to be a clinical problem.

For exchange transfusions of infants, CPD blood is recommended because of its more physiological pH and its better maintenance of red cell oxygen transport. CPD blood can be used for exchange transfusions after several days of storage without concern about 2,3-DPG levels. This

†2, 3-DPG: micro moles/gm hemoglobin.

is particularly helpful in situations where fresh blood is difficult to obtain. Because CPD contains 15% less citrate to bind calcium ions, it is recommended that the dose of calcium gluconate be reduced to 0.85 ml of 10% solution for each 100 ml of blood.

Coagulation Factors and Platelets in CPD Blood

There is no significant difference between the amounts of coagulation factors in fresh CPD blood compared to fresh ACD blood and the changes in coagulation factors during storage are identical in CPD and ACD blood.^{9,10} For treatment of bleeding disorders, CPD blood is equivalent to ACD blood stored for a similar period of time.

The yield of Factor VIII in cryoprecipitate depends upon the pH of the original plasma.¹² Since acidified plasma reduces the yield of Factor VIII, it was anticipated that the higher pH of CPD plasma would result in improved Factor VIII content of these cryoprecipitates. Although neither Graybeal, et al.⁹ nor Shanberge et al.¹³ found

improved Factor VIII recoveries from CPD plasma, the Factor VIII content of cryoprecipitate was essentially equal in CPD and ACD plasma.

Platelets prepared from CPD blood have a slightly greater tendency to clump, because of the higher pH. However, present methods of platelet preparation result in very little platelet clumping so that the platelets prepared from CPD blood are similar in quantity and have similar *in vivo* recovery and survival as those from ACD blood.¹¹

Summary

Compared to ACD anticoagulant, CPD has the following advantages for blood preservation (1) isotonicity for red blood cells, thus minimizing the lesion of collection and resulting in improved red blood cell survival, (2) more physiological pH, (3) 15% less citrate ion, and (4) improved red cell oxygen transport. Many blood banks are now beginning the routine use of CPD in blood collections. This should result in an improved blood product for patient therapy.

Specialized Care for Acute Myocardial Infarction

Four-Year Experience in a Community Hospital

DANIEL E. HILL, M.D.;* RICHARD F. SCHROECKENSTEIN, B.S.* and
JAMES N. KARNEGIS, M.D., PH.D.*

THE CONCEPT of the coronary care unit has been widely accepted.¹⁻⁸ The organization and policies of these units vary somewhat from hospital to hospital as to the type of patient admitted, length of patient stay, etc.

In making plans for the facility to serve our hospital we believed the scope should not be arbitrarily limited only to patients with coronary disease. It seemed to us that the advantage offered by such units was the collection of cardiac patients in one geographic site and their continuous electrical and medical surveillance from a central point. Such a facility might be expected to be useful for patients with a wide variety of cardiac problems. Our facility was named Cardiac Monitor Central (CMC), a term we believe to be accurately descriptive.

The United Hospitals-Miller Division is a 400 bed community hospital. It was planned that any member of the medical staff could admit a patient to the facility, but it was required that the patient be under the primary care of a member of the Department of Internal Medicine. The CMC was under the supervision of a cardiologist (JNK) who as a full-time staff physician was available for consultation. We were in the position of being able to collect information about the patient population to whom such a unit would be of service and in answering several questions. These included the ability of the physician at the time of admission to correctly diagnose a myocardial infarction in a patient generally known to him in his private practice and to characterize clinically and pathologically the patient who did sustain a myocardial infarction.

Methods

Admissions

The CMC was designed for all cardiac patients, although postoperative cardiovascular patients were usually cared for in another area. The bulk of the patients admitted had or were suspected of having an acute myocardial infarction. Other patients with serious arrhythmias or suspected of having arrhythmias or requiring intensive cardiovascular care and surveillance were admitted also. The patients were cared for by their individual internists, and there were no established standard policies for diagnosis or treatment. There were no arbitrary restrictions on age, condition of patient, or length of stay in the unit.

Of the 1,225 admissions to the CMC from April, 1967 to April, 1971 (Table 1), 451 fulfilled the criteria for myocardial infarction which will be discussed in the next section. Of the remaining 774 patients, 434 were admitted to rule out acute myocardial infarction and were found to have myocardial ischemia without infarction with or without congestive heart failure, or other disease including pulmonary embolism, gastroenteritis, cholecystitis, pericarditis, pancreatitis, herpes zoster, or influenza. Two hundred one patients were admitted primarily for the monitoring of cardiac

This study was supported by Public Health Service Research Grant 5 RO1 HL05694 and Research Training Grant 5 TO1 L05570 from the National Heart and Lung Institute.

Address for Reprints: James N. Karnegis, M.D., United Hospitals-Miller Division, 125 W. College Avenue, St. Paul, Minnesota, 55102.

rhythm; the diagnoses for these patients included Adams-Stokes syndrome, heart block due to arteriosclerotic heart disease, paroxysmal atrial tachycardia, rapid atrial fibrillation, faulty pacemaker, and cerebrovascular accident. Ninety-six patients were admitted with acute congestive heart failure with or without arrhythmias secondary to digitalis toxicity, rheumatic heart disease, hypertension, or emphysema. Twenty-one patients were admitted following operative or postoperative cardiac arrest (usually noncardiac operations) or arrhythmias without infarction. There were 22 admissions for miscellaneous reasons.

Of the 774 patients without myocardial infarction, 35 suffered cardiac arrest while in the cardiac monitoring unit, and seven of them were successfully resuscitated (20% resuscitation rate). The average stay in the cardiac monitoring unit for the patients without infarction was 3.3 days with a range of one to 29 days.

Criteria for Diagnosis of Acute Myocardial Infarction

The triad of elements most useful in the diagnosis of acute myocardial infarction includes angina pectoris, sequential electrocardiographic changes, and alteration in the concentration of certain serum enzymes. The patients in this study accepted in the category of acute myocardial infarction demonstrated one of the following combinations: (1) a history of angina pectoris and classic electrocardiographic changes, (2) angina pectoris and typical serum enzyme changes, or (3) electrocardiographic and enzyme changes without typical angina pectoris. The diagnosis of subendocardial infarction was made when the clinical history was associated with the electrocardiographic signs of progressive acute ST-segment depressions or symmetric T-wave inversions.

The precise diagnosis of acute myocardial infarction is not always possible with present techniques. Among patients considered to have acute myocardial infarction, some false positives can be

ACUTE MYOCARDIAL INFARCTION CARE

expected, i.e., patients without actual infarction. Similarly, among patients considered free from infarction, some false negatives can be expected, i.e., patients who actually do have myocardial infarction. Lown and co-workers⁹ have demonstrated that the error due to false positive diagnoses will be small if the diagnostic criteria just listed are adhered to whereas the error due to false negative diagnoses will be much larger. They reported that autopsies on patients who did not meet the criteria for acute infarction revealed that 25% actually had acute infarcts. Lindberg and associates¹⁰ reported that 15 to 20% of patients with acute myocardial infarctions may not be symptomatic. On the other hand, patients with acute coronary insufficiency may have symptoms exactly like those who have true myocardial infarction.

The case records of the 451 patients who met the criteria for the diagnosis of acute myocardial infarction were studied with reference to the incidence and prognostic effects of age and sex, preexisting disease, distribution of electrocardio-

graphic pattern of infarction, arrhythmia, and other complications. Mortality and causes of death were examined also and the mortality rate was compared with those reported from other hospitals.

Results

The Acute Myocardial Infarction

Population

Of the 451 consecutive patients admitted to the cardiac monitoring unit who were diagnosed as suffering from acute myocardial infarction, 278 were male with a mean age of 62.5 years, and 173 were female with a mean age of 69 (Table 2). A past history of coronary disease was common since 55% had a history of angina and 36% had had a previous myocardial infarct. Nineteen percent had a history of chronic congestive heart failure; hypertension existed in 34% and diabetes in 20%.

The average length of stay in CMC for the 451 infarct patients was 5.8 days with a range of one to 21 days.

Electrocardiographic Changes in the Acute Myocardial Infarction Population

Classic electrocardiographic changes were seen in 339 patients (75%), with anterior (32%) and inferior (30%) patterns being nearly equally prevalent. Subendocardial infarction occurred in 78 patients (17%). The remaining patients had a pattern of old infarction which remained unchanged (7%) or had no diagnostic electrocardiographic changes (nearly 1%). The distribution of these patterns is similar to that in the 300 consecutive patients studied by Lown and co-workers.⁹

Arrhythmias in the Acute Myocardial Infarction Population

In this study we followed the method of classifying arrhythmias suggested by Lown and associates.⁹ This method offers the advantage of relating the arrhythmia to the underlying clinical situation so that a system of therapy is provided. The first category of arrhythmia is that of manifest electrical instability and includes ventricular extrasystoles and ventricular tachycardia. The second category is that of potential electrical instability and includes sinus bradycardia, nodal extrasystoles, nodal rhythm, and heart block. The third major category is the arrhythmias of pump failure which have the common denominator of arising from left ventricular "pump failure." These include sinus tachycardia, atrial extrasystoles, atrial tachycardia, atrial flutter, and atrial fibrillation.

Of the 451 patients with acute myocardial infarction, 89% (401 patients) exhibited arrhythmias. The results are summarized in Table 3. A large number (62%) exhibited either rare or frequent ventricular extrasystoles. This is similar to reports of others.^{11,12} The relative incidence of the various other arrhythmias is comparable to that in these published reports with a few exceptions. Notably, the percentage of patients displaying ventricular tachycardia, sinus bradycardia, third degree heart block, sinus tachycardia, and atrial extrasystoles was lower in this series, sometimes by half, but nevertheless significant numbers of patients did have these conditions.

Fifteen patients (3%) developed complete heart block following the infarction, and 11 of these (73%) exhibited an inferior or posterior-inferior infarction. Similar findings have been reported in the literature.¹¹

Ventricular fibrillation or asystole occurred either primarily or secondarily in 108 patients (24%). The incidence of ventricular fibrillation

and asystole in this series was high compared to some reports.^{9,11} Whereas Day¹³ reported a 14% incidence of ventricular fibrillation in 273 patients Lown's group⁹ reported an incidence of electrical failure of only 2% among their 300 patients. Lown and co-workers also emphasized in this regard the importance of abolishing minor arrhythmias of ventricular origin, of recognizing the potential electrical instability caused by the presence of bradycardia, of controlling heart blocks, and of treating early incipient heart failure.

In this study of the 108 patients with ventricular fibrillation or asystole, the arrhythmia was primary in 84. Of these, 27 survived the electrical failure and were discharged from the hospital, a successful resuscitation rate of 32%. Other successful resuscitation rates as reported vary from 13 to 67% (Table 4).

Prognostic Effects of Various Clinical Factors

Features of the population sample which may affect prognosis include sex, age, prior coronary artery disease, development of heart failure, hypotension, and the various arrhythmias.

The overall mortality rate in the 451 cases of acute myocardial infarction was 22%. The mortality rates available from the literature are tabulated in Table 4 and they range from 14 to 32%. In the extensive study of Hofvendahl from Sweden,⁶ the coronary care unit mortality rate of 17% was compared with a concurrent control hospital mortality rate of 35%.

Among the females in our series, the mortality rate was 32%, which was twice that of the males (16%). Of the 99 deaths, 44 occurred in males and 55 in females. This contrasts to the ratio of males to females of 1.6 in the total group of 451 patients. In addition, a greater than average mortality rate became evident a decade earlier for females than for males and remained higher for females in each decade thereafter. For females, the mortality rate increased from 15% in the age decade of the fifties to 36% in the sixties, while for males it went from 13% in the sixties to 29% in the seventies. This leads to the conclusion that age and sex are significant in the case of acute infarction in that prognosis is poor at an earlier age in women than in men. This finding differs from some reports^{19,20} and agrees with others.²¹

With respect to preexisting disease a high mortality rate (45%) was found for those patients

ACUTE MYOCARDIAL INFARCTION CARE

having a past history of congestive heart failure. The mortality rate was also higher than the overall average for those with a past history of hypertension (32%) or old infarction (30%). As a group, patients with preexisting diabetes had a slightly higher than average mortality rate (28%). There was a sharp difference, however, when these patients were divided according to sex. Among females with diabetes the overall mortality rate was 39%, while among males it was 15%.

The mortality rate for patients showing electrocardiographic signs of acute infarction involving the anterior as well as the inferior surfaces of the heart was almost double the average mortality, being 38%. Those with an electrocardiographic pattern of old infarction also had an increased mortality rate (34%). It is interesting that the electrocardiographic pattern diagnosis of acute inferior infarction was associated with a lower

overall average mortality rate (16%) than the entire group. Acute subendocardial infarction carried a lower mortality (14%).

Table 3 shows that an increased mortality rate was associated with ventricular tachycardia, nodal rhythm and, in general, with those arrhythmias associated with pump failure. Among all patients with acute myocardial infarction, left ventricular failure is a common complication and it was observed in 40% of the patients in this series. Frank pulmonary edema occurred in 18% of all cases. Congestive heart failure carried a mortality of 30 to 52%, depending upon severity. Cardiogenic shock is one of the most serious complications of acute myocardial infarction and, in this series, hypotension, shock, and renal failure carried grave prognoses with mortality rates of 57, 75, and 76%, respectively.

TABLE 4
Summary of Mortality Rates in Various Hospitals from Literature Including
The United Hospitals—Miller Division*

Hospitals	No. of Myocardial Infarctions	Period Covered	Avg. Days Monitored	Mortality		Resuscitation	
				Control Patients %	Monitored Patients	Attempts	Successes
Toronto General Hospital, Canada ¹⁴	789	Mar. 13, 1962 to Mar. 12, 1967	5	40	235(30%)		16(15%)

*A portion of this Table has been reported by Trajano and associates¹.

†Initial 100 patients and subsequent 150 patients, respectively.

ACUTE MYOCARDIAL INFARCTION CARE

Of the 451 patients with myocardial infarction admitted to the CMC, 99 died during hospitalization; 79 of these 99 patients (80%) died in the CMC. Of those dying in this unit, 42 (53%) had been admitted within less than six hours from onset of symptoms and a total of 81% had been admitted within 24 hours from onset of symptoms (Table 5). The time interval from admission to death in

the central monitoring unit ranged from four hours to greater than two weeks with 57 (72%) of the patients dying within the first six days (Table 6 *Causes of Death* (Table 7)

The cause of death is here defined as the underlying basis initiating the sequence of events leading to death. Primary electrical failure accounted for more than half or 57 of the deaths; in 35 of these cases, heart failure was present. Forty-four of those deaths occurred in the CMC and 13 in general wards of the hospital after the patients were transferred from the unit. Half (30) of these deaths occurred after the first week of hospitalization. In one case of ventricular fibrillation, hypokalemia was apparently associated, while in one case of asystole complete atrioventricular block was associated.

Pump failure manifesting generally as shock was the cause of death in 34 patients. All but two of these deaths occurred in the CMC and the majority occurred in the first six days after hospitalization. In ten cases (nine of them in women), demise occurred over a very short period of time and autopsies revealed ventricular rupture. Lown and associates¹¹ have termed this phenomenon "complete pump failure" whereby the patient

Total	14	17	27	25	16	79	20	99

does not appear critically ill until the moment of death. The results are similar to those reported in the study done by Hofvendahl.⁶

Autopsies were performed on 60 of the 99 patients (61%). Coronary atherosclerosis was extensive in all cases (Grade 3 to 4) and cardiomegaly was noted in about one-third of the cases. Pulmonary congestion, edema, or both were found in about half of the cases. The majority of those dying of electrical failure had old healed areas of infarct as well as an acute process.

An acute myocardial infarct was recognized anatomically in 48 of the autopsied cases. A fresh coronary artery thrombus was found in another three cases, but no acute myocardial infarct was recognized in these three cases although areas of healed infarction were present. In another seven cases, only areas of healed infarction were recognized with additional complicating processes including aortic stenosis, hypertension, aortic insufficiency with cystic medial necrosis, and previous Vineberg procedure. No infarct was revealed in two cases with the cause of death being acute dissecting aortic aneurysm with rupture.

Discussion

The great majority of the patients (72%) were admitted to the CMC because of the suspicion of a myocardial infarction. In patients generally known to him in his private practice, the attending physician at the time of admission was able to correctly

predict the presence of myocardial infarction about one-half of the time (51%). Most of the remaining 28% of admissions were for various arrhythmias or congestive heart failure.

Analysis of the data reveals certain findings which are particularly noteworthy. The average mortality rate for all patients with myocardial infarction was 22%. Females had an overall mortality rate twice that of males, a higher than average mortality rate a decade earlier than males, and a much higher mortality rate than males when diabetes was present. It was of interest that nine of the ten cardiac ruptures occurred in females.

With regard to preexisting disease, congestive failure carried the highest mortality rate, followed by hypertension and old infarction. Arrhythmias occurred in 89% of the patients with ventricular extrasystoles having the highest incidence. Congestive heart failure, hypotension, shock and renal failure were the complications that carried the gravest prognosis.

In this study, a large proportion of the deaths (57 of the 99) occurred from primary electrical failure with or without heart failure. Most of these failures occurred in the CMC, and half occurred after one week of hospitalization. Even though the successful resuscitation rate of 32% (27 of 84 attempts at resuscitation) is comparable with the average rates reported by other coronary care units, deaths from this cause are still high. From this study, it seems possible that the mortality rate can be further reduced by placing greater emphasis on the prevention and vigorous treatment of cardiac arrhythmias.

Mike Finamore was told he had leukemia. Nine years ago.

When Mike Finamore was thirteen years old, he was told he had leukemia.

At that time, this meant he had five, maybe six months, to live.

But just about then, leukemia research produced some dramatic results:

A special combination of drugs that would kill the leukemia cells in the blood and permit the person to live longer than ever before.

So Mike was treated. And it worked.

He didn't die.

Instead, he became one of the fortunate few to have leukemia and live. And today his weekly treatments enable him to lead a normal life.

In fact, right now he's putting the roof on a house he built himself.

And when it's finished there will be a double celebration.

The new house. And Mike's 22nd birthday.

Most people expect presents. Mike's happy just to have a birthday.

We want to wipe out cancer in your lifetime. Give to the American Cancer Society.

Mexican Arthritis Clinics

A Statement by the Committee on Rheumatic Diseases
of the Minnesota State Medical Association

The Committee on Rheumatic Diseases has been asked by a number of physicians to comment on the Mexican arthritis treatment centers which are attracting a considerable amount of public interest in Minnesota as they have elsewhere in the country. The lay press has published descriptions of these clinics. One of the most recent articles was printed in the NATIONAL OBSERVER on June 13, 1973. Both the American Medical Association and the American Rheumatism Association are attempting to obtain factual data to present to the medical profession. This is not easy. Details about treatment used have not been published in reputable medical journals by the attending physicians at these clinics. Nor have these facts been made readily available otherwise to the medical profession.

The State Committee on Rheumatic Diseases has learned that a number of arthritis treatments are established along the Mexico-United States border. Known centers exist in Mexicali near Calexico, California, Piedras Negras near Eagle Pass, Texas, Juarez near El Paso, Texas, Nogales near Tucson, Arizona, and Tecate near San Diego. In addition, the widely publicized treatment (Liefport) previously available at the clinic of Dr. Robert Liefmann of Montreal is now available at a branch of that clinic opened in Mexico City.

Patients who have attended these centers have reported their experience and have provided samples of the drugs which have been analyzed. These patients describe the experience as follows: After a brief interview with an attending physician who takes a history of the rheumatic problem and examines the joints, laboratory studies of blood or urine may be done. Following this, most of the patients have been given a prescription for medicines which they are told to have filled in one of the nearby pharmacies. In some cases, injections of drugs have been given at the "clinic." The nature of the medicines has not been fully explained to the patients we have talked with. Many of these patients, fearing the use of steroids, have asked the physician at the arthritis treatment center about

the nature of the drugs recommended and have been told that the drugs did not contain "cortisone." There is reason to believe, however, judging not only from the evident side effects of hypercortisonism but from identification or chemical analysis of the tablets that a significant proportion of the medicines prescribed are in fact an adrenocorticosteroid.

Samples of these drugs for which patients have paid amounts ranging from \$100 to several hundred dollars for a six month supply have been identified as steroids (cortisone acetate, methylprednisolone, dexamethasone, triamcinolone, etc.), tranquilizers (Valium, Stelazine), monoamine-oxidase inhibitors (Parnate), analgesics such as acetaminophen, dipyrone, antihistamines (chlorpheniramine), male and female sex hormones, and dimethyl sulfoxide (DMSO). The directions patients have been given for using these medicines—and especially for reducing or discontinuing the medication after a period of use—have been sketchy at most.

There is no doubt but that many of these drugs taken in large doses will "cover up" much of the pain and discomfort of inflammatory arthritides such as rheumatoid arthritis and even of degenerative joint disease. But none of these medicines are cures. The side effects, while varying from patient to patient, may be dangerous. Among the serious side effects in some patients with rheumatoid arthritis have been a devastating progression of rheumatoid vasculitis. In others, a rapid irreversible joint destruction has occurred. Such joint destruction can be expected also in some patients with degenerative joint disease who overuse the damaged joints when the warning sign of pain is decreased.

Some patients (and some members of the press) ask, "Isn't it worth the risk of dangerous side effects from these powerful drugs if one can get some relief of the pain and disability of arthritis even though it be only temporary?" "Why not buy now, pay later?" The answer is that the price,

in terms of permanent disability and increasing pain, is too great in the long run. Ultimately, it falls to the patient's home physician to "pick up the pieces" when the initial benefits are gone and the patient's situation is worse than it was when he sought the miraculous cure in Mexico. Only rarely is arthritis sufficiently painful and disabling that our current treatment measures are ineffective. Even in these situations there is little evidence to show that the massive drug therapy advised in these Mexican arthritis treatment centers is beneficial over the months or years which typify the course of chronic arthritis. There is considerable evidence that the results of such prolonged and massive steroid therapy are bad.

Minnesota physicians who are asked to care for patients who have been treated at these Mexican border clinics would do their profession and their patients a great service by documenting as much as possible the facts about this treatment and forwarding it to the American Rheumatism Association. The Committee on Rheumatic Diseases is interested also in learning of these facts and would be happy to assist in transferring the information to the American Rheumatism Association.

Mexican Arthritis Drugs

The following list describes a number of dosage forms for drugs which were analyzed in the Food

and Drug Administration Laboratory in Minneapolis. These drugs were submitted by arthritics or their physicians and were presumably purchased in Mexicali, Mexico. Because many of the dosage forms appeared frequently, this list was prepared to aid in the identification of these drugs.

The dimensions and weights are based upon the relatively few drugs submitted and may not be statistically significant. Coated tablets and capsules will undoubtedly deviate most from the data given. It should be emphasized that the drug content, particularly for the capsule forms, could be changed in the future. It may also be possible that drug forms exist which may be similar in appearance but contain other ingredients than those given in this list. Therefore, the conclusions reached, based upon appearance alone, should be used with some reservation.

The description of tablets is in the following sequence: coating, top view, side view, type of coloring (i.e., solid, speckled, etc.), color, marking, and scoring. The number and color description appearing in parentheses refers to *JAMA* 182, 12:1146 (Dec. 22, 1962), "Identification Guide for Solid Dosage Forms" by John J. Hefferen, which also contains some of the descriptive terms in this list. The color descriptions can be most accurately defined by referring to the standard color chart in the *Journal*.

Key:

Tablets

- Description: Uncoated, round, flat with bevel, solid, white, unmarked,* scored $\frac{1}{2}$. Diameter: 8.0 mm, center thickness: 2.8 mm; edge thickness: 2.35 mm.

Weight: 175 mg.

Comments: *Some tablets marked . Unmarked tablets have been sold as ibuprofen ("Motrin").

Contents: 16 β -methylprednisone acetate.
- Description: Uncoated, round, flat with bevel, solid, light green (No. 32, green), unmarked, scored $\frac{1}{2}$. Diameter: 8.1 mm, center thickness: 2.75 mm, edge thickness: 2.15 mm.

Weight: 180 mg.

Contents: 16 β -methylprednisone acetate.

MEXICAN ARTHRITIS CLINICS

3. Description: Uncoated, round, flat with bevel, solid, pale peach (No. 13, red), marked **M**, scored $\frac{1}{2}$. Diameter: 8.0 mm, center thickness: 2.35 mm, edge thickness: 1.6 mm.
Weight: About 180 mg.
Contents: Diazepam ("Valium").
4. Description: Uncoated, round, flat with bevel, very slightly speckled, brown (No. 16, brown), unmarked, scored $\frac{1}{2}$. Diameter: 8.2 mm, center thickness: 2.8 mm, edge thickness: 2.1 mm.
Weight: 170 mg.
Contents: 16 β -methylprednisone acetate.
5. Description: Uncoated, round, flat with bevel, yellow, marked **H**, scored $\frac{1}{2}$. Diameter: approx. 7.1 mm, center thickness: 2.8 mm, edge thickness: 2.25 mm.
Weight: Approx. 140 mg.
Contents: Unknown.
6. Description: Uncoated, round, yellow (No. 34, yellow, slightly lighter), marked **L**, impressed, scored $\frac{1}{2}$. Diameter: 6.37 mm, center thickness: 4.50 mm, edge thickness: 2.0 mm.
Weight: 115 mg.
Contents: Mepenzolate bromide.
7. Description: Uncoated, biconvex, pale green (No. 33, green), unmarked, unscored. Diameter: 10.4 mm, center thickness: 5.25 mm, edge thickness: 2.5 mm.
Weight: 450 mg.
Contents: Tetracycline hydrochloride.
8. Description: Uncoated, flat with bevel, white, marked **Lepetit**, scored $\frac{1}{2}$. Diameter: 12.8 mm, center thickness: 3.9 mm, edge thickness: 2.9 mm.
Weight: 565 mg.
Contents: Meproamate.
9. Description: Coated, oblong, somewhat biconvex (side view), dark pink (No. 30 red), white core, unmarked. Length: 17.4 mm, width: 9.7 mm, thickness: 6.1 mm.
Weight: 840 mg.
Contents: Meproamate.
10. Description: Coated, round, biconvex, pale green (No. 31, green, but lighter), white core, unmarked. Diameter: 9.0 mm, thickness: 4.8 mm.
Weight: 290 mg.
Contents: Chlordiazepoxide.
11. Description: Coated, round, biconvex, pale green (No. 31, green), pale brown mottled (No. 16, brown) core, marked **SKF** in red. Diameter: 9.9 mm, thickness: 3.9 mm.
Weight: 330 mg.
Contents: Trifluoperazine ("Stelazine").
12. Description: Coated, round, biconvex (somewhat oblong), light brown (No. 21, brown), white core, unmarked. Diameter: 8.0 mm, thickness: 4.7 mm.
Weight: 220 mg.
Contents: Oxyphenbutazone.
13. Description: Clear, colorless, conventional-shaped, unmarked, hard gelatin, No. 3 capsule, containing white powder.
Weight: Gross capsule weight: 350 mg, contents: 300 mg.
Contents: Hydrocortisone, hydrocortisone acetate.
14. Description: Clear, colorless, conventional-shaped, unmarked, hard gelatin No. 2 or No. 3 capsule, containing white powder.
Weight: Gross capsule weight: 300 mg, 380 mg, contents: 250 mg, 320 mg.
Contents: 16 β -methylprednisone acetate.
15. Description: Clear, colorless, conventional-shaped, unmarked, hard gelatin, No. 2 capsule, containing yellow powder.
Weight: Gross capsule weight: 370 mg, contents: 310 mg.
Comments: Contents is nonuniform in color; appears to be mixture of white and yellow powders. Contents: Unknown, possible steroid.

**She came from a nice quiet town
to find something stronger than marijuana.**

A lot of small towns think they
don't have any drug problem.
Because their drug problems
move away. And die someplace
else.

The cancer of drug addiction

has spread throughout the country
and we're not going to wipe it out
overnight.

But let's do something.
Let's get started. Troubled
teenagers are among the people in

this town who are crying out for
our help.

Poor people, sick people, old
people, disturbed people are
counting on us.

Give the United Way. Please.

If you don't do it, it won't get done.

"Third-World" Health

JAMES D. FETT, M.D., M.P.H.*

THE HARSH REALITY of grossly inadequate medical care so prevalent in wide areas of the developing countries, the "Third-World," cannot be appreciated by considering only a statistical presentation of the need.

In many areas of the "have-not" nations no statistical data are even available. Misery, poverty, illness, and death follow their progression without entering the statistical mill.

When data are available (inadequate though they may be) we have a glimpse of the chasm which divides the "developed" world from the developing world:

- (a) Per capita income (1970)¹: U.S.A. \$4,262 compared to under \$300 in many nations: Tanzania \$91, Indonesia \$107, Kenya \$130, Mauritius \$222, Paraguay \$230, Korea \$241, Ecuador \$247.
- (b) Crude death rate per 1000 population (1970)²: U.S.A. 9.4 compared to greater than 20 in 42 nations of whom 35 are African and seven Asian. (range: Lesotho 21—Upper Volta 29.1).
- (c) Infant death rate per 1000 live births (1970)²: U.S.A. 19.8 compared to greater than 75 in 47 nations of whom 36 are African and seven Asian. (range: Bolivia 77.3—Zambia 259).
- (d) Population per medical school³: U.S.A. 2,100,000 compared to Asia 5,500,000 and Africa 14,900,000.
- (e) Population per physician (1971)⁴: U.S.A. 669 compared to greater than 10,000 in 48 nations of whom 32 are African and 13 Asian. (range: Angola 10,363—Upper Volta 92,759).

Because of uneven physician distribution population per physician data do not indicate the low level of care available. Urban areas may have well under 1000 population per physician while rural areas in the same country have in excess of 100,000 per physician.^{5,6} A few nations in the developing world, even in the face of urgent needs unmet in many areas, actually are exporters of physicians because of political, economic, and professional conditions.⁷

Health needs in the developing world are difficult to conceptualize if one is not directly exposed

to those needs. Only as "developed" nations' medical personnel cross the boundary into areas of abject need does an emotional reaction and realization of needs occur. Responding to the needs entails certain important emphases which include:

1. *The necessity that medical education and training be adapted to the social, medical, and economic conditions existing in each country.*⁸

An excellent example is the Haile Selassie I Public Health College and Training Center at Bondor, Ethiopia,⁹ where personnel are trained as a team who will be able to work in diverse regions and situations within the country.

It would be unrealistic to project a goal of achieving the placement of a physician for each village. This is neither attainable nor desirable for too often the physician would be unable to carry out the work for which his training prepares him. In such a setting one must consider the importance of regional medical centers as well as the essential role of medical assistants, sanitary officers, diploma nurses, and other auxiliary medical personnel. One must further encourage the concept of health team, recognizing the value and importance of each member.^{10,11}

2. *The necessity to coordinate activities through National Health Ministries in developing countries.*

In the international health scene one is impressed by the array of assisting agencies varying in the extent and emphases of their participation as well as being of diverse origins, from governments (national and international, i.e., United Nations), to private foundations, to church-related ventures. Not infrequently their efforts are poorly coordinated, sometimes valuable efforts being wasted in terms of ultimate accomplishments.

It would seem reasonable that this coordination would be carried out by each National Health Ministry. This would help to avoid unnecessary duplication of efforts both in training and of care, with resultant inefficient use of already limited personnel. This would also involve the placement of medical centers in the best utilizable location, avoiding both what would appear to be competitive facilities in any one area as well as areas

*School of Auxiliary Medical Personnel, Vanga Hospital, Vanga, Republic of Zaire and University of Minnesota Unit in Internal Medicine, Northwestern Hospital, Minneapolis, Minnesota. Address reprint requests to Dr. Fett, 221 S. Madison, Pierre, S.D. 57501.

See editorial, page 969.

completely destitute of care.

3. *The necessity for continuing and expanding relationships between United States medical programs in developing nations (not necessarily limited to medical schools) aimed towards the development of indigenous health personnel.*

A desirable goal could be that each medical school would recognize the mutual value of and engage in a contracted relationship with a medical school or program in a developing country. Could not each American school through a coordinating agency, such as the Association of American Medical Colleges, relate itself to a nation with great needs and mutually create programs which (again) point towards developing indigenous medical personnel?

Numerous examples of relationships already exist: the Rochester-Lagos faculty exchange, the Tulane-Columbia program in medical education, the Duke University programs in international health, the Indiana University-Jinnah (Pakistan) Postgraduate Medical Center relationship, the Albany Medical College-Georgetown Hospital, British Guiana, clinical exchange, the University of Kansas, University of Philippine's Student-Faculty exchange,¹² and the Seoul National University cooperative project with the University of Minnesota, including programs in medicine.^{14,15} One would need to encourage funding through U.S. Aid and/or various private foundations.

4. *The necessity to encourage continuing exchange of medical graduates and trainees between the developing and "developed" nations.*

Aside from the primary aim of helping to meet urgent needs, exposure to medical needs in developing areas has a solutary effect upon our young medical graduates and trainees. The consequent broadening of understanding of the world community's needs, the increased awareness of oppressive health burdens borne by many populations in developing countries, the intercultural experiences gained, must all be considered as assets to the returning participant and to his further contribution as he establishes himself in whatever role it may be in medicine.

This participation would certainly be facilitated if each medical school center has a related coun-

terpart in a developing nation. Such a relationship would also permit developing nations' trainees to participate in programs in this country. Their participation has increased value when done on the post-graduate level (at which time the trainee is familiar with medical needs in his country) and with a definite time limitation so that his training in this country is useful to the development of his own country and that the program is not simply encouraging a "brain-drain" on his country.

5. *The necessity for continuing and increasing recognition of the importance of the role of preventive medicine combined with the development of family planning services so that advances are not eliminated by soaring populations.^{11,13}*

Natural population increase rate (excess of crude birth rate per 1,000 population over crude death rate per 1000 population) exceeds 20 in 48 African nations and 33 Asian nations compared to rates of 8.8 in the U.S.A., 4.4 in the United Kingdom, and 1.7 in the Federal Republic of Germany.²

When advances in health services and development of economies are slow as is often the case it is clear that these advances can be quickly erased with rapid increases in population. While this is readily understood by individuals in favored situations, for those in situations in which death from infectious and parasitic diseases is a common occurrence, particularly among children under five years of age, there will be no receptivity to birth control programs. One must first demonstrate the ability to preserve the life of these infants.

The purely hospital-oriented, disease-treatment oriented approach clearly has not been able to do this. The importance of the role of preventive medicine in the developing nations is now recognized. Where health budgets are severely limited (many developing nations have less than \$1 per inhabitant annually available for health expenditure¹¹) programs in the preventive medicine field have far greater yields in terms of population benefits per dollar expenditure. This does not exclude the role and importance of clinical medicine but again emphasizes the importance of careful coordination of programs.

Conflict Society and the Profession of Medicine*

GEORGE B. MARTIN, M.D.†

SOCIETY IS ASKING what we are doing to improve the public health and why is what we are doing so expensive. People believe that if we are pressured enough we can and will deliver care to meet the public expectation.

The physician is acknowledged as society's only member educated and trained to evaluate a person's total health status, to determine what is likely to happen to that person, and to formulate what, if anything, may be done to alter that course. The physician diagnoses, prognoses, and manages, not the patient, but the problem that makes a person a patient. As the years pass, we find increasing restriction, regulation, obstruction, and change being instituted by society and its politics which not only force us to function differently but occasionally decrease our ability to carry out our prime responsibility. The physician knows that inadequate nutrition, poor housing and working conditions, pollution, poverty, poor education, lack of genetic counselling, racism, drugs, alcohol, promiscuity, and a passive acceptance of accidental and highway death and injury, when coupled with society's improper use and abuse of services now available, all contribute to ill health. He is relatively powerless to affect any of these, but the record shows he has altered many of them to a higher degree than most professions.

Medicine knows that within 30 years the total body of knowledge available will be fourfold that of 1970 and it is making genuine progress in the effort to assimilate and make it usable. The traditional work ethic of physicians is changing. The commitment to the 70 hour work week is disappearing and the search for fringe benefits and a higher quality of family and social life is gaining momentum. Increased government programs eliminate the charity patient; and the end of the exploitive practices involving the health care worker as decreased total productivity and increased costs of health care delivery. Changing patterns of payment for health and medical care have greatly altered educational funding practices at a

time when the educational process is being reviewed and altered substantially, thus causing increased burdens on the educational segments of our profession.

Medicine's ethic of reverent regard for each human life until death can no longer be thwarted, often finds itself in conflict with the emerging ethic of health and well being of society and humanity as a whole, which is assuming a compelling importance as a condition of the quality of life for our species. Undoubtedly these ethics will accommodate each other. Hopefully medicine's contribution to this resolution will be sufficient to preserve basic humanistic qualities in society's ethical structure. What is this society of ours? Why over the past 20 to 30 years do we find ourselves in the midst of strange and unsettling times? Who or what is responsible? It is even now difficult to find common agreement on basic ingredients of right and wrong.

Society would appear to be losing its individualism, its self. It is losing faith in long established institutions and organizations. Society is searching for meaning, often times by faulting the old while groping for something new. Society is trying to escape from freedom rather than be lost as a selfless individual. The old is crumbling, the new not yet established. A specific legislator is OK but as a politician he is not OK. My physician is OK. AMA or organized medicine is not OK.

Our congested highly mobile society has passed the stage of industrialization and is in the throes of technocracy and bureaucracy. According to Topfler, we are on the verge of "ad-ocracy" with its ever increasing narrowing of specialization and affluence generally increasing. The cult of youthfulness and the "nowness" of need satisfaction are with us and are exploited by politicians, social innovators as well as the advertising media. These circumstances lead to disappearance of old values and they are causing rootlessness. If you work for a large impersonal organization, live in crowded circumstances, make few friends and are then separated from them; when your family is somewhere else as is your church and school, and you haven't a strong sense of self and self-com-

*Speech delivered to the House of Delegates at the Annual Meeting of the Minnesota State Medical Association, May 23, 1973.

†Past-President of Minnesota State Medical Association.

petency, you become, as it were, alienated from the old and even from yourself. This is a terrifying state for most people. To escape it, you seek pleasure, physical and material. You seek reassurance, usually from your physician, clergyman, or friends. You seek new roots which now seem to be special interest groups, social or political, consumer groups, unions, activist groups, anywhere you can feel accepted, comfortable—*rooted!*

The dependency on new values and groupings with its usual concurrent passive-aggressive characteristics develops, complete with the helpless anger. The wave of anti-intellectualism, collectivistic solutions to problems and backdoor, meaning legislated, humanism, i.e., the right to health, knowledge, money and good feelings, completes the picture of the alienated, cynical society demanding product accountability, civic, social and financial responsibility with amorphous public control applied to all its institutions, organizations and government. Society now is rejecting the intellectual, paternalistic decisions as to what is best or right or proper for it.

Do you wish some examples? A few pertinent ones: lay representation on professional examining boards, professional union developments, retroactive denial of Medicare benefits, increased demand for tranquilizers and instant cures, increased malpractice suits and settlements, minimalization of professional input into planning activities. Do they sound familiar?

What should our course of action be? What principles do we adopt to guide us as we diagnose, prognose, and manage our patients' problems and thereby hopefully enrich our society?

To me there is but one simple answer with many complicated ramifications thereof. *Humanism* is the answer. The basic concept of selfhood for all within the boundaries of protection of others' rights and privileges. Our patients are individuals and should be acknowledged as such. When they are lacking that quality we cannot give it to them, but we may help them to find it. We must refrain from managing people and their lives. We must instead help them manage the problems that brought them to us and we must recognize their right to refuse our counsel even though the risks they run by so doing are numerous. When in fact they are not capable of judging for themselves, we must be careful that our dis-

agreement with their choice is not the cause of forced management but that course of action truly is the result of their inability to make human judgments.

No one can legislate feelings or the way society will act. Institutions cannot force society molds at will. No organization can by itself dictate exactly what is good or right for society.

I propose that in understanding our society as physicians become radical activists standing for the human condition of individualism and development of self-determination with all its associated anxieties, for this is *truly freedom*. We must as individuals and organizations adhere to intellectual honesty and the ethics of human dignity and then in spite of philosophical divergence on individual points speak out loud and clear for freedom of self and others, our patients, our society realizing always that many will disagree with us and that is their right.

If you wish one example that exemplifies society's state today, its alienation, its searching for meaning, its conflicted ethical structure as well as one complicated ramification of my simple principle of humanism, I suggest that you contemplate the recent Supreme Court decision concerning abortion.

If you recognize Frohm, Reick, Topfler, Novak Rogers and many others in this text, you are perceptive. To borrow from yet another, John Millis I submit we should deemphasize the curative aspects of our profession and accentuate the *caring*. First and foremost, we should care about our patients for if our motivation is otherwise, we are not worthy to care for them. If we do not care about them, we will be dogmatic, paternalistic and manipulative. By caring about and for them, we will be supportive and enhance their growth and thereby society's maturation.

Times are changing, states the sage. Will we as a profession regret the change and wish it were as of old? Will we utilize our capabilities merely to cope with the changes; or will we actively undertake to understand the human condition (*that's diagnosis*); extrapolate to where it's leading (*that's prognosis*); and have the guts to put ourselves in the middle of conflict to promote humanization (*that's management*). That is what being a physician today requires. Are we equal to it? Do we as a profession hear Thoreau's distant drummer and shall we try to hold his cadence?

Laboratory Letter

Computer Integrated Thyroid Tests

I shall explain the reasons for a computer program that does the following:

1. lists diagnostic possibilities for PBI, T-4 (Murphy-Patte) and T-3;
2. calculates thyroid indices (PBI X T-3, or T-4 (M-P) X T-3);
3. gives messages under certain conditions.

These messages include a list of contaminating substances when the PBI exceeds 20 mcg.%; notes indicating that free thyroid indices are a better measure of thyroid function than PBI, T-4 (M-P), or T-3 considered alone; another note saying the free thyroid index is normal and therefore the patient is euthyroid; and finally, a suggestion to order a T-4 (M-P) when the PBI is elevated.

Why use a computer to integrate thyroid tests and to give these messages?

Well, for openers, relationships between PBI, T-4 (M-P), and T-3 are tough to remember. At least this is true for most of us. Maybe you're better at it. Anyway, look at Table 1 to refresh yourself. In Table 2 note the practical consequences of these relationships.

TABLE 1
Relationships between Thyroid Tests

Common Conditions Effecting Tests				Free Thyroid Indices	
	PBI	T-4 (M-P)	T-3	PBI X T-3	T-4 (M-P) X T-3
Normal Persons	Normal	Normal	Normal	Normal	Normal
Hyperthyroidism	Increases	Increases	Increases	Increases	Increases
Hypothyroidism	Decreases	Decreases	Decreases	Decreases	Decreases
Hormones (Pregnancy, Estrogen, Oral Contraceptives, etc.)	Increases	Increases	Decreases	Normal	Normal
Diseases or Drugs, Increasing Thyroxine Binding Globulin	Increases	Increases	Decreases	Normal	Normal
Diseases or Drugs, Decreasing Thyroxine Binding Globulin	Decreases	Decreases	Increases	Normal	Normal
Iodine or Iodide Contamination in Euthyroid Persons	Increases	Normal	Normal	Increases	Normal

TABLE 2
Summary of Thyroid Test Results
in 100 Consecutive Patients on Whom PBI, T-4 (M-P), and T-3 Ordered.

	PBI	T-4 (M-P)	T-3	PBI X T-3	T-4 (M-P) X T-3
	69	84	79	84	94
Normal (Euthyroid Range)					
Increased (Hyperthyroid Range)	20*	5	12	5	3
Decreased (Hypothyroid Range)	11	11	9	6	3
Total	100	100	100	95†	100

*Includes five contaminated PBIs over 20 mcg.% and eight borderline values between 8.0 and 8.8 mcg.%. Because of the many borderline high values, we suspect upper limit of 8.0 mcg.% may be set too low.

†Total less than 100 because computer does not calculate PBI X T-3 when PBI contaminated.

LABORATORY LETTER

As you can see from these tables, there is no single thyroid function test that will give you a true picture of thyroid status under all circumstances. But if you're ordering only one, T-4 (M-P) is probably the best.

Probably the best combination of thyroid tests to order is T-4 (M-P) and T-3 with a calculated free thyroid index ($T-4 \times T-3$).

Which brings us back to the original question: Why the computer for thyroid function tests?

Simple enough.

The computer saves you the time and trouble of:

1. remembering normal ranges;
2. integrating thyroid tests with each other and with other tests;
3. calculating and comparing thyroid indices; and,
4. recalling, on-the-spot, the reasons why for differences or inconsistencies between results.

The following seven figures (retyped from actual printouts) will serve to illustrate what has just been said.

Richard L. Reece, M.D.
Minneapolis, Minnesota

Normal Tests	Value	Normal Range
Calcium	9.7	8.3 - 10.3
Phosphorus	3.4	2.2 - 4.5
Glucose	116.	68. - 125.
Bun	17.0	5.8 - 23.0
Uric Acid	4.4	2.0 - 8.5
Bilirubin	.6	.2 - 1.1
Cholestrol	263.	118. - 300.
Total Prot	7.3	5.5 - 8.0
Albumin	4.3	2.8 - 4.9
Globulin	3.0	1.8 - 3.6
A/G Ratio	1.4/1	.7 - 1.8
LDH	142.	76. - 212.
SGOT	24.	8. - 48.
ALK Ptase	55.	16. - 91.
PBI	5.4	4.0 - 8.0
T3	33.0	25.0 - 35.0
T4	5.3	3.5 - 8.5
FTI (PBIT3)	178.	100. - 280.
FTI (T4T3)	175.	87. - 297.

All tests normal for age and sex.

Diagnostic possibilities based solely on tests

Order of list does not imply probabilities

List is not necessarily complete

Fig. 1—Sample of output. All thyroid tests normal.

Normal Tests	Value	Normal Range
Calcium	9.2	8.6 - 10.3
Phosphorus	3.2	2.3 - 4.5
Glucose	108.	73. - 123.
Bun	17.0	4.5 - 21.9
Uric Acid	4.7	1.9 - 7.4
Bilirubin	.5	.2 - 1.1
Cholestrol	227.	129. - 268.
Triglyc	112.	10. - 160.
Total Prot	7.5	6.1 - 7.9
Albumin	3.8	3.5 - 5.0
A/G Ratio	1.0/1	.9 - 2.0
LDH	156.	79. - 212.
SGOT	19.	8. - 48.
ALK Ptase	51.	9. - 84.
T3	25.0	25.0 - 35.0
T4	7.6	3.5 - 8.5
FTI (PBIT3)	207.	100. - 280.
FTI (T4T3)	190.	87. - 297.
Sodium	136.	135. - 147.
Potassium	4.1	3.5 - 5.5

Abnormal Test	Value	Normal Range	St Dev Away From Normal
---------------	-------	--------------	-------------------------

PBI	High	8.3	4.0 - 8.0	1
Globulin	High	3.7	1.8 - 3.6	1

All abnormal tests are borderline and may be physiological and clinically insignificant.

The free thyroxine index PBI times T3 is normal, indicating that the patient is euthyroid.

High PBI may be due to pregnancy, estrogens, oral contraceptives, hepatitis, acromegaly or iodides.

Possibilities

High globulin

Diagnostic possibilities

Acute or chronic inflammation

Hyperlipoproteinemia

Degenerative vascular disease

Alcoholism

Macroglobulinemia

Collagen disease

Sarcoid

Liver disease

Analbuminemia

Cryoglobulinemia

Plasma cell myeloma

Diagnostic possibilities based solely on tests

Order of list does not imply probabilities

List is not necessarily complete

Fig. 2—Sample of output. Only PBI abnormal, and even then only borderline high. Free thyroid index (PBI x T-3) indicates patient euthyroid. A typical thyroid pattern for patient taking oral contraceptives, or in pregnancy.

THYROID TESTS

Normal Tests	Value	Normal Range
Calcium	8.5	8.1 - 10.2
Phosphorus	3.4	1.9 - 4.3
Glucose	99.	77. - 134.
Uric Acid	9.4	3.1 - 9.5
Bilirubin	.5	.2 - 1.2
Cholestrol	190.	100. - 252.
Total Prot	6.3	5.3 - 7.7
Albumin	3.3	2.8 - 4.8
Globulin	3.0	1.9 - 3.4
A/G Ratio	1.1/1	.7 - 2.0
LDH	190.	68. - 221.
SGOT	43.	8. - 48.
T3	35.0	25.0 - 35.0
FTI (PBIT3)	105.	100. - 280.
FTI (T4T3)	101.	87. - 297.

Abnormal Test	Value	Normal Range	St Dev Away From Normal
ALK Ptas High	100.	25. - 85.	2
PBI Low	3.0	4.0 - 8.0	2
Bun High	26.0	9.7 - 25.6	1
T4 Low	2.9	3.5 - 8.5	1

The free thyroxine index PBI times T3 is normal, indicating that the patient is euthyroid.

Low PBI may be due to nephrotic syndrome, chronic disease, acromegaly, cytomel, acth, cortisone, methyltestosterone, mercurial diuretics, salicylates, dilantin, chlorpromazine.

The free thyroxine index T3 times T4 is normal, indicating that the patient is euthyroid.

Low T4 may be due to anti thyroid drugs, T3 therapy (cytomel), dilantin, high doses of salicylates, testosterone, acth, corticosteroids, diseases depressing thyroxine-binding globulin, hereditary thyroxine-binding deficiency.

Possibilities

Non-fasting specimen

High: Bun ALK Ptas

Degenerative vascular disease (CHF, arteriosclerosis, hypertension)

High: Bun ALK Ptas

Serum artifact (old overheated too long on clot)

High: ALK Ptas

Hepatic or biliary damage (EG drug hepatitis or cholecystitis)

High: ALK Ptas

Renal Insufficiency

High: Bun ALK Ptas

Prerenal Azotemia (Chf, Shock, etc.)

High: Bun ALK Ptas

Regional Enteritis

High: ALK Ptas

Osteomalacia, rickets or vitamin D deficiency

High: ALK Ptas

Steatorrhea

High: ALK Ptas

Alcohol ingestion or alcoholic hepatitis

High: ALK Ptas

Pancreatitis

High: ALK Ptas

Tissue necrosis, IE abscess, gangrene, peritonitis, etc.

High: ALK Ptas

Collagen disea, especul lupus and lupus hepatitis

High: ALK Ptas

Bone Metastases

High: ALK Ptas

Metastatic tumor in liver

High: ALK Ptas

Pseudohypoparathyroidism

High: ALK Ptas

Pulmonary embolism or infarction or bronchopneumonia

High: ALK Ptas

Carcinoma

High: ALK Ptas

Pagets Disease

High: ALK Ptas

Ulcerative colitis

High: ALK Ptas

Acromegaly

High: ALK Ptas

Prolonged immobilization

High: ALK Ptas

Diagnostic possibilities based solely on tests

Order of list does not imply probabilities

List is not necessarily complete

Fig. 3—Portion of printout. Pattern from 75-year-old man chronically ill from heart failure. Although PBI and T-4 low, both thyroid indices normal, indicating euthyroid state. Pattern due to drugs, such as aspirin, occupying thyroxine-binding sites on globulin. For reasons we cannot yet explain, low PBI, low T-4, and high T-3 is a common pattern in elderly people.

Normal Tests	Value	Normal Range
Calcium	9.7	8.6 - 10.3
Phosphorus	3.2	2.3 - 4.5
Glucose	83.	72. - 122.
Bun	10.0	4.2 - 21.7
Uric Acid	3.1	1.8 - 7.4
Bilirubin	.4	.2 - 1.1
Cholestrol	188.	125. - 263.
Triglyc	130.	10. - 160.
Total Prot	6.9	6.1 - 7.9
Albumin	3.9	3.5 - 5.0
Globulin	3.0	1.8 - 3.6
A/G Ratio	1.3/1	.9 - 2.1
LDH	106.	77. - 210.
SGOT	20.	8. - 48.
ALK Ptas	64.	8. - 83.

Abnormal Test	Value	Normal Range	St Dev Away From Normal
PBI Low	1.6	4.0 - 8.0	3
T4 Low	1.3	3.5 - 8.5	2
FTI (PBIT3) Low	37.	100. - 280.	2
FTI (T4T3) Low	30.	87. - 297.	2
T3 Low	23.0	25.0 - 35.0	1

The free thyroxine index PBI times T3 is Abnormal. Since it is more reliable than PBI or T3 it is being used to consider diagnostic possibilities.

The free thyroxine index T3 times T4 is abnormal. Since it is more reliable than T3 or T4, it is being used to consider diagnostic possibilities.

Possibilities

Hypothyroidism

Low: FTI (PBIT3) FTI (T4T3)

Diagnostic possibilities based solely on tests

Order of list does not imply probabilities

List is not necessarily complete

Fig. 4—Hypothyroid pattern.

Normal Tests	Value	Normal Range
Calcium	9.0	8.3 - 10.3
Phosphorus	2.8	2.2 - 4.5
Glucose	105.	68. - 125.
Bun	13.0	5.6 - 22.8
Uric Acid	5.1	2.0 - 8.4
Bilirubin	.4	.2 - 1.1
Cholestrol	194.	117. - 300.
Total Prot	6.7	5.5 - 8.0
Albumin	4.2	2.9 - 4.9
Globulin	2.5	1.8 - 3.6
A/G Ratio	1.7/1	.8 - 1.8
LDH	149.	76. - 211.
SGOT	30.	8. - 48.
ALK Ptas	33.	15. - 90.
T3	32.0	25.0 - 35.0
FTI (T4T3)	102.	87. - 297.

Abnormal Test	Value	Normal Range	St Dev Away From Normal
PBI Low	3.0	4.0 - 8.0	2
T4 Low	3.2	3.5 - 8.5	1
FTI (PBIT3) Low	96.	100. - 280.	1

The free thyroxine index PBI times T3 is abnormal. Since it is more reliable than PBI or T3 it is being used to consider diagnostic possibilities.

The free thyroxine index T3 times T4 is normal, indicating that the patient is euthyroid.

Low T4 may be due to anti thyroid drugs, T3 therapy (cytomel), Dilantin high doses of salicylates, testosterone, ACTH, corticosteroids, diseases depressing thyroxine-binding globulin, hereditary thyroxine-binding deficiency.

FTI (PBIT3) and FTI (T3T4) disagree. Because of possible iodine contamination FTI (T3T4) will be used.

Possibilities

Diagnostic possibilities based solely on tests

Order of list does not imply probabilities

List is not necessarily complete

Fig. 5—Thyroid pattern of 55-year-old woman. Note that PBI x T-3 is slightly low, but T-4 (M-P) x T-3 in low borderline range. In situation like this, only physician can judge if patient is hypothyroid.

LABORATORY LETTER

Normal Tests	Value	Normal Range	
Calcium	9.3	8.6 - 10.3	
Phosphorus	4.4	2.2 - 4.5	
Glucose	97.	74. - 128.	
Bun	13.0	7.3 - 24.2	
Uric Acid	5.3	2.2 - 7.9

Abnormal Test	Value	Normal Range	St Dev Away From Normal
T3 High	36.0	25.0 - 35.0	1

All abnormal tests are borderline and may be physiological and clinically insignificant.

The free thyroxine index T3 times T4 is normal, indicating that the patient is euthyroid.

High T3 may be due to liver disease, metastatic tumor, nephrosis, pulmonary insufficiency, aortic stenosis, atrial arrhythmia, diseases that depress plasma protein levels coumadins, androgens, cortisone, large doses of aspirin.

Diagnostic possibilities based solely on tests

Order of list does not imply probabilities

List is not necessarily complete

Fig. 7—Example of printout when PBI contaminated. If this occurs, PBI not used in calculating free thyroid index. Because of frequency and unpredictability of iodine contamination, many laboratories have stopped doing the PBI test.

Minnesota State Medical Association

121st Annual Meeting of the Minnesota State Medical Association will be held in Duluth, May 16 and 17, in the Duluth Arena-Auditorium.

A MINNPAC INVITATION

The MINNESOTA MEDICAL POLITICAL ACTION COMMITTEE invites you to support the singularly most effective means available to make medicine's voice heard in the political arena—MINNPAC/AMPAC.

Join MINNPAC today. Participate in the political and governmental process which will ultimately determine how the practice of medicine will be structured during this decade. Your \$25.00 includes both MINNPAC and AMPAC dues and will be used to assist in electing responsible men and

women in both parties to the State Legislature and to Congress. The MINNPAC Board of Directors is charged with the responsibility of urging physicians and their wives to become actively involved in the support of candidates and the party of their choice. **YOUR help is needed NOW!** Complete the application form or merely send your \$25.00 check to: MINNPAC, Metro Medical Building, 825 South 8th Street, Room 503, Minneapolis 55404.

P.S. Those of you who have already sent your check—*Thank You!*

- ☐ Please bill me \$25.00 for my annual membership in MINNPAC and AMPAC.
☐ Membership contribution is enclosed.

Book Reviews

WE MAINLINE DREAMS by Judianne Densen-Gerber, J.D., M.D. Doubleday & Company. \$9.95.

Judianne Densen-Gerber, Doctor of Jurisprudence from Columbia University and Doctor of Medicine from New York University, is a controversial woman. "We Mainline Dreams," her story of Odyssey House in New York and now with branches elsewhere, is controversial but fascinating, and worth reading. In its rambling, somewhat "scrapbook" style, it has much to offer the physician. We know so pathetically little about what that book deals with so movingly, so irritatingly, so distressingly. Childhood and adolescent addiction has been Dr. Densen-Gerber's central concern, but in "We Mainline Dreams" that is just one part of a far-reaching sociomedical story.

For the physician, perhaps the most meaningful segment is that written by Dr. Charlie Rohrs, endocrinologist-turned-Medical Director of Odyssey House. He writes: "In school or during their training, doctors aren't taught about addiction except in the same negative way that a policeman sees it. You see the worst aspects and get a picture of addicts as operators, hostile people demanding treatment, criminals, smugglers of drugs onto the ward, people you couldn't possibly identify with and shouldn't waste hospital beds on . . . That's not the way they're seen at Odyssey. Here we see them as human beings who have a sickness that's different from other people's. I learned to consider the drug addict as a person with a treatable disease rather than someone sub-human. . . . The concepts of a therapeutic community like Odyssey House are applicable to absolutely everybody. There's no one who couldn't benefit from it, and I'm including the professional class most definitely. The addicts aren't people who can't function, as is so often expressed. They function very well, manipulating and exploiting to change situations to suit themselves. The problem is their functioning isn't constructive functioning. Their tragedy is that they destroy other people—every single patient in his program has torn his family to pieces—and in the process of destroying others, they destroy themselves. They problem-solve in an inadequate way rather than a healthy way. And so do many others in society who are considered well."

There is an idea current in medicine—in much of society, for that matter—that active concern with addicted

people demands that the non-addicted people be completely accepting and totally permissive. Listen a bit more to Charlie Rohrs: "The basic pathology in most addicts is that they treat other people as objects, not as persons. They are insensitive to other people's feelings, and therefore they can't monitor their own conduct by the pain they may cause other human beings. In short, they don't care . . . We have to supply values . . . Here, we tell (the addict) that he has to pay the consequences. He cannot continue to hurt others. Kindness is withheld when kindness is not deserved. He can't get well unless we make demands, and we can't treat him unless he faces reality."

The story of addiction is a sordid story, and most of us will choose to go on ignoring it, if not actively avoiding it. For those who choose otherwise, this book should provide a few broadening and disturbing hours.

R. G. B. Bjornson, M.D.
St. Paul, Minnesota

ON ACID HUMOR ARISING FROM FOODS AND ON WHITE MAGNESIA. By Joseph Black, 1754. Translated by Thomas Hanson, 1973.

This small book is a translation from the latin of the inaugural medical dissertation by Joseph Black, a physician who became one of the celebrated chemists of the 18th Century. The first portion is devoted to an essay on digestion as it was understood at that time, and the second portion to an analysis of the properties of magnesium carbonate. In this thesis, Black describes the experiments which eventually laid to rest the phlogiston theory and led to the discovery of carbon dioxide.

It is one of the first experiments utilizing a balance for quantitative chemical analysis, and has been described as being second in importance only to Newton's "Optics" as a model for philosophical investigation. It is one of the milestones in man's understanding of himself and the world which surrounds him.

This translation was accomplished to commemorate the 75th birthday of Professor Owen Wangersteen. It is amply annotated and may be read with little difficulty.

at Christmas'

Reinhold O. Goehl, Jr., M.D.

DECEMBER, 1973

Everybody experiences psychic tension.

Most people can handle this tension.

Some people develop excessive psychic tension and need your counseling,

and a few may need counseling
and the psychotropic action of Valium® (diazepam).

Before deciding to make Valium (diazepam) part of your treatment plan, check on whether or not the patient is presently taking drugs and, if so, what his response has been. Along with the medical and family history, this information can help you determine initial dosage, the possibility of side effects and the ultimate prospects of success or failure.

While Valium can be a most helpful adjunct to your counseling, it should be prescribed only as long as excessive psychic tension persists and should be discontinued when you decide it has accomplished its therapeutic task. In general, when dosage guidelines are followed, Valium is well tolerated (see Dosage). For convenience it is available in 2-mg, 5-mg and 10-mg tablets.

Drowsiness, fatigue and ataxia have been the most commonly reported side effects.

Until response is determined, patients receiving Valium should be cautioned against engaging in hazardous occupations requiring complete mental alertness, such as driving or operating machinery.

Before prescribing, please consult complete product information, a summary of which follows:

Indications: Tension and anxiety states; somatic complaints which are concomitants of emotional factors; psychoneurotic states manifested by tension, anxiety, apprehension, fatigue, depressive symptoms or agitation; symptomatic relief of acute agitation, tremor, delirium tremens and hallucinosis due to acute alcohol withdrawal; adjunctively in skeletal muscle spasm due to reflex spasm to local pathology, spasticity caused by upper motor neuron disorders, athetosis, stiff-man syndrome, convulsive disorders (not for sole therapy).

Contraindicated: Known hypersensitivity to the drug. Children under 6 months of age. Acute narrow angle glaucoma; may be used in patients with open angle glaucoma who are receiving appropriate therapy.

Warnings: Not of value in psychotic patients. Caution against hazardous occupations requiring complete mental alertness. When used adjunctively in convulsive disorders, possibility of increase in frequency and/or severity of grand mal seizures may require increased dosage of standard anti-convulsant medication; abrupt withdrawal may be associated with temporary increase in frequency and/or severity of seizures. Advise against simultaneous ingestion of alcohol and other CNS depressants. Withdrawal symptoms (similar to those with barbiturates and alcohol) have occurred following abrupt discontinuance (convulsions, tremor, abdominal and muscle cramps, vomiting and sweating). Keep addiction-prone individuals under careful surveillance because of their predisposition to habituation and dependence. In pregnancy, lactation or women of childbearing age, weigh potential benefit against possible hazard.

Precautions: If combined with other psychotropics or anticonvulsants, consider carefully pharmacology of agents employed; drugs such as phenothiazines, narcotics, barbiturates, MAO inhibitors and other antidepressants may potentiate its action. Usual precautions indicated in patients severely depressed, or with latent depression, or with suicidal tendencies. Observe usual precautions in impaired renal or hepatic function. Limit dosage to smallest effective amount in elderly and debilitated to preclude ataxia or oversedation.

Side Effects: Drowsiness, confusion, diplopia, hypotension, changes in libido, nausea, fatigue, depression, dysarthria, jaundice, skin rash, ataxia, constipation, headache, incontinence, changes in salivation, slurred speech, tremor, vertigo, urinary retention, blurred vision. Paradoxical reactions such as acute hyperexcited states, anxiety, hallucinations, increased muscle spasticity, insomnia, rage, sleep disturbances, stimulation have been reported; should these occur, discontinue drug. Isolated reports of neutropenia, jaundice; periodic blood counts and liver function tests advisable during long-term therapy.

Dosage: Individualize for maximum beneficial effect.

Adults: Tension, anxiety and psychoneurotic states, 2 to 10 mg b.i.d. to q.i.d.; alcoholism, 10 mg t.i.d. or q.i.d. in first 24 hours, then 5 mg t.i.d. or q.i.d. as needed; adjunctively in skeletal muscle spasm, 2 to 10 mg t.i.d. or q.i.d.; adjunctively in convulsive disorders, 2 to 10 mg b.i.d. to q.i.d. **Geriatric or debilitated patients:** 2 to 2½ mg, 1 or 2 times daily initially, increasing as needed and tolerated. (See Precautions.) **Children:** 1 to 2½ mg t.i.d. or q.i.d. initially, increasing as needed and tolerated (not for use under 6 months).

Supplied: Valium® (diazepam) Tablets, 2 mg, 5 mg and 10 mg; bottles of 100 and 500. All strengths also available in Tel-E-Dose® packages of 1000.

acute arthritic inflammation...heat that freezes

In acute rheumatoid arthritis consider Tandearil. The anti-inflammatory action of Tandearil quickly helps reduce heat, pain, swelling, and stiffness. Results are usually seen in 3 or 4 days. Try it for a week when the symptoms defy aspirin control.

Remember that Tandearil is not a simple analgesic. It should not be used on patients responding to routine therapy. Before using, please read the prescribing information. It's summarized below.

Tandearil® helps take the heat off

Oxyphenbutazone NF

Geigy

Tablets of 100 mg.

Important Note: This drug is not a simple analgesic. Do not administer casually. Carefully evaluate patients before starting treatment and keep them under close supervision. Obtain a detailed history, and complete physical and laboratory examination (complete hemogram, urinalysis, etc.) before prescribing and at frequent intervals thereafter. Carefully select patients, avoiding those responsive to routine measures, contraindicated patients or those who cannot be observed frequently. Warn patients not to exceed recommended dosage. Short-term relief of severe symptoms with the smallest possible dosage is the goal of therapy. Dosage should be taken with meals or a full glass of milk. Patients should discontinue the drug and report immediately any signs of: fever, sore throat, oral lesions (symptoms of blood dyscrasias); dyspepsia, epigastric pain, symptoms of anemia, black or tarry stools or other evidence of intestinal ulceration or hemorrhage, skin reactions, significant weight gain or edema. A one-week trial period is adequate. Discontinue in the absence of a favorable response. Restrict treatment periods to one week in patients over sixty.

Contraindications: Acute gouty arthritis, rheumatoid arthritis, rheumatoid spondylitis.

Contraindications: Children 14 years or less; mild patients; history or symptoms of G.I. inflammation or ulceration including severe, current or persistent dyspepsia; history or evidence of drug allergy; blood dyscrasias; renal, hepatic or cardiac dysfunction; hypernephrosis; thyroid disease; systemic edema; dermatitis and salivary gland enlargement due to the drug; polymyalgia rheumatica and temporal arteritis; patients receiving other potent immunotherapeutic agents, or long-term anti-inflamatory therapy.

Warnings: Age, weight, dosage, duration of therapy, existence of concomitant diseases, and concurrent potent chemotherapy affect incidence of toxic reactions. Carefully instruct and observe the individual patient, especially an aging (forty years and over) who have increased susceptibility to the toxicity of the drug. Use lowest effective dosage. Weigh potential unpredictable benefits against po-

tential risk of severe, even fatal, reactions. The disease condition itself is unaltered by the drug. Use with caution in first trimester of pregnancy and in nursing mothers. Drug may appear in cord blood and breast milk. Serious, even fatal, blood dyscrasias, including aplastic anemia, may occur suddenly despite regular hemograms, and may become manifest days or weeks after cessation of drug. Any significant change in total white count, relative decrease in granulocytes, appearance of immature forms, or fall in hematocrit should signal immediate cessation of therapy and complete hematologic investigation. Unexplained bleeding involving CNS, adrenals, and G.I. tract has occurred. The drug may potentiate action of insulin, sulfonamides, and sulfonamide-type agents. Carefully observe patients taking these agents. Nontoxic and toxic goiters and myxedema have been reported (the drug reduces iodine uptake by the thyroid). Blurred vision can be a significant toxic symptom worthy of a complete ophthalmological examination. Swelling of ankles or face in patients under sixty may be prevented by reducing dosage. If edema occurs in patients over sixty, discontinue drug.

Precautions: The following should be accomplished at regular intervals: Careful detailed history for disease being treated and detection of earliest signs of adverse reactions; complete physical examination including check of patient's weight; complete weekly (especially for the aging) or an every two week blood check; pertinent laboratory studies. Caution patients about participating in activities requiring alertness and coordination, as driving a car, etc. Cases of leukemia have been reported in patients with a history of short- and long-term therapy. The majority of these patients were over forty. Remember that arthritic-type pains can be the presenting symptom of leukemia.

Adverse Reactions: This is a potent drug; its misuse can lead to serious results. Review detailed information before beginning therapy. Ulcerative esophagitis, acute and reactivated gastric and duodenal ulcer with perforation and hemorrhage, ulceration and perforation of large bowel, occult G.I. bleeding with anemia,

gastritis, epigastric pain, hematemesis, dyspepsia, nausea, vomiting and diarrhea, abdominal distention, agranulocytosis, aplastic anemia, hemolytic anemia, anemia due to blood loss including occult G.I. bleeding, thrombocytopenia, pancytopenia, leukemia, leukopenia, bone marrow depression, sodium and chloride retention, water retention and edema, plasma dilution, respiratory alkalosis, metabolic acidosis, fatal and nonfatal hepatitis (cholestasis may or may not be prominent), petechiae, purpura without thrombocytopenia, toxic pruritus, erythema nodosum, erythema multiforme, Stevens-Johnson syndrome, Lyell's syndrome (toxic necrotizing epidermolysis), exfoliative dermatitis, serum sickness, hypersensitivity angitis (polyarteritis), anaphylactic shock, urticaria, arthralgia, fever, rashes (all allergic reactions require prompt and permanent withdrawal of the drug), proteinuria, hematuria, oliguria, anuria, renal failure with azotemia, glomerulonephritis, acute tubular necrosis, nephrotic syndrome, bilateral renal cortical necrosis, renal stones, ureteral obstruction with uric acid crystals due to uricosuric action of drug, impaired renal function, cardiac decompensation, hypertension, pericarditis, diffuse interstitial myocarditis with muscle necrosis, perivascular granulomata, aggravation of temporal arteritis in patients with polymyalgia rheumatica, optic neuritis, blurred vision, retinal hemorrhage, toxic amblyopia, retinal detachment, hearing loss, hyperglycemia, thyroid hyperplasia, toxic goiter, association of hyperthyroidism and hypothyroidism (causal relationship not established), agitation, confusional states, lethargy; CNS reactions associated with overdosage, including convulsions, euphoria, psychosis, depression, headaches, hallucinations, giddiness, vertigo, coma, hyperventilation, insomnia; ulcerative stomatitis, salivary gland enlargement.

Statement on Antisubstitution Laws and Regulations

The purpose of this statement is to affirm the support of the participating organizations for the laws, regulations and professional traditions which prohibit the unauthorized substitution of drug products.

Traditionally, physicians, dentists and pharmacists have worked cooperatively to serve the best interests of patients. Productive cooperation has been achieved through mutual respect as well as a common concern for the ideals of public service. This mutual respect has been fostered, in part, by joint support over the years for the adoption and enforcement of laws and regulations which prohibit unauthorized substitution and encourage joint discussion and selection of the best drug supply of drug products. The basic principles of medical, dental and pharmacy practice are thus maintained and preserved in the interest of patient welfare.

The antisubstitution laws have obstructed enhancement of the professional status of pharmacy any more than they have in and of themselves guaranteed absolute protection from unsafe drugs, or freed physicians, dentists and pharmacists from their responsibilities to patients. A practical matter, however, such laws and regulations encourage interprofessional communications regarding drug product selection and assure the profession the opportunity to use fully its expertise in drug selection to the advantage of patients.

Physicians and dentists should be urged to increase the frequency and regularity of their contacts with pharmacists in selection of quality drug products, recognizing that

economies to patients can be improved through such communication, taking into account the patients' needs. The pharmacist's knowledge of the chemical characteristics of drugs, their mode of action, toxic properties and other characteristics that assist in making drug selection decisions should be utilized to the fullest extent practicable by physicians and dentists in serving their patients.

Since drug product selection entails knowledge derived from clinical experience, the physician's and dentist's roles in product selection remain primary and do not permit delegation of decisions requiring medical and dental judgments. A broader role in therapy will evolve for pharmacists as improved understanding and cooperation among the professions continue to grow.

There has been no evidence that there are convincing reasons to modify or repeal existing laws and regulations prohibiting the unauthorized substitution of another drug product for the one specified by a prescriber. It is our belief that such laws and regulations merit the joint support of the medical, dental and pharmaceutical professions and the pharmaceutical industry.

Add your opinion to the weight of other professionals and send it to your state assemblyman or legislator.

President's Letter

HMO

The other evening my friend, Ted Sweetser, said to me as we were leaving the Medical Arts building, "What would you think about an HMO restaurant?" To one who in his youth expressed reproductive capacity with somewhat greater than average enthusiasm, the notion is intriguing. Indeed, what about an HMO grocery store, or an HMO shoe store, or an HMO University of Minnesota where for one fee all the children would be educated; or an HMO automobile industry where all the ills that beset one's car could be remedied for a single, annual fee, or indeed an HMO government where each of us could pay an identical annual fee for whatever government services were needed.

The fact is that this egalitarian ideal, while attractive in some ways during periods of great need, is not so attractive during periods of great contribution. Thus, many who by dint of good fortune or good education or good effort earn somewhat more than neighbors, contribute more taxes for the same or possibly even less public services. So, in the public sector one pays according to ability and receives according to need. The HMO concept is that each one pays the same but receives in varying amounts.

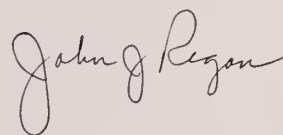

The general HMO concept may have value but how can this be determined without study. The great rush to set up a new system of medical delivery without extensive survey of the old or research into the new seems ill-advised. It was Will Durant in "The Story of Civilization" who pointed out that with evolution or revolution man arrives at the same place at about the same time. So why the bloodshed? If evolution of a social institution produces the same result in improvement of that institution why not let evolution run its course?

That seems to be what is happening in the medical system. Some of the changes we have seen have been for the better. Not all have. Some of the problems that exist in the distribution of medical care and in the rising costs of that care can be traced directly to attempts at reforming the system and in developing painless methods of pay-

ing for care. The worker in the factory whose medical care is paid for by an employer may not directly write a check to Blue Cross or Blue Shield but this cost is a result of his work. At the same time his abuse of that system for paltry or nonexistent causes contributes enormously to the cost and comes, if not directly, at least indirectly out of his toil and sweat. The point is that not all reforms are good reforms. Not all revolutions are good revolutions but that most evolution is a pretty good way at arriving at the desired long term goal.

None of us could criticize the general medicare concept that the oldsters in our population deserve care. All of us can criticize many of the methods used to deliver that care and many of the injustices that are being perpetrated in the guise of concern for our senior citizens. The deprivation of those citizens of their own privacy, the denial of claims for certain kinds of care, the abdication of medicare's responsibility for the very real needs of many of these folks for long term custodial management when the neurons have faltered and the orientation is deficient would be reprehensible in the private sector and certainly is more reprehensible in the public sector.

So, if we overcommit ourselves immediately to some revolutionary system which is not only untried but certainly unproved, we may find ourselves at some distant future date longing for the good old days when there were less bureaucrats, less clerks, less actuarial experts and less politicians involved in the dispensing of care to the sick.

Respiratory Failure in Influenza Pneumonia

Treated with Membrane Oxygenator

E. SPENNY, M.D.,* S. GESUNDHEIT, M.D.,* P. GANNON, M.D.†
and E. LINDBERG, M.D.†

MEMBRANE OXYGENATORS have been in clinical use for several years as part of the system for extracorporeal circulation in open-heart surgery.¹⁻³ More recently membrane oxygenators have supported patients in profound acute respiratory insufficiency.⁴⁻⁶ They produce less blood trauma than other oxygenators, permitting perfusions lasting several days.

Influenza pneumonia has been responsible for cases of periodic fulminating diffuse pneumonia

producing acute respiratory insufficiency and death.⁷ Three such cases were subjected to venovenous perfusion with a membrane oxygenator⁴ with temporary improvement but all three ultimately succumbed.

This case illustrates that it is possible to effect recovery in profound respiratory insufficiency using venoarterial perfusion with a portable membrane oxygenator in a community hospital.

Case Report

A 46-year-old man was admitted to Unity Hospital, Fridley, on February 1, 1972, with the chief complaint of progressive shortness of breath and coughing. He had been seen three days earlier by his private physician. A

*Department of Medicine, Unity Hospital, Fridley, Minnesota.

†Thoracic and Cardiovascular Surgery, Minneapolis, Minnesota.

Request for reprints should be sent to Dr. Edward Spenny, 3620 Central Avenue Northeast, Minneapolis, Minnesota 55418.

Fig. 1—Portable chest film immediately after tracheostomy on evening of admission showing diffuse bilateral opacities.

chest film at that time showed minimal right lower lobe infiltration, and a leukocyte count was 8,700 with 88% polymorphonuclear leukocytes. Ampicillin 250 mg. four times daily was prescribed. However, his symptoms progressed.

On admission he had marked cyanosis, fever of 39°C., respiratory rate of 40, radial pulse of 120, bilateral moist rales and distended neck veins. Oxygen administration was ineffective due to restlessness and disorientation. The blood arterial oxygen tension was 33 mm.Hg. and his cyanotic color deepened with paroxysms of non-productive cough. During tracheostomy a prolonged grand mal seizure occurred. Copious pink frothy fluid was aspirated from the trachea. The central venous pressure was 23 cm. water; the chest Xray showed bilateral opacities (Figure 1). Following the intravenous administration of morphine sulfate (15 mgm.), furosemide (40 mgm.), digoxin (0.75 mgm.), hydrocortisone (100 mgm.), and phlebotomy (560 cc.), the central venous pressure dropped to 8 cm. of water. A diuresis of 3,200 cc. resulted. After being on the Bennett MA-1 Volume Respirator for 20 minutes with 100% oxygen the arterial blood oxygen tension was 37 mm.Hg. The patient was transferred to the Intensive Care Unit while the membrane oxygenator was assembled at the bedside.* In spite of the use of maximal ventilation of 1000 cc. tidal volume delivering 100% oxygen at 35 cm. water pressure the arterial blood oxygen fell to 27 mm.Hg. His appearance became ashen. The slightest stimulation would trigger paroxysms of coughing. It was concluded that the patient was in imminent danger of asphyxiation and venoarterial perfusion with the membrane oxygenator was instituted after systemic heparinization.

Perfusion was done by cannulating the iliac vein and axillary artery and oxygenation of the blood with two three-meter-square Lande-Edwards Membrane Oxygenators (Figure 2). A constant flow of 1.3 liters per minute was maintained and the patient's condition stabilized. The arterial pO_2 from the left radial artery was 31 mm.Hg. The venous oxygen tension was 20 mm.Hg. and the oxygen tension of the blood leaving the oxygenator was 207 mm.Hg. During this time maximal ventilation was continued with 100% oxygen, 1000 cc. tidal volume with 35 cm. water pressure at a respiratory rate of 20-22 per minute for the next 48 hours.

Initially the heart rate was about 80 with a normal sinus rhythm. The blood pressure ranged from 90 to 95 mm.Hg. systolic. All peripheral pulses were diminished but present. He was maintained on digitalis. The venous pressure was kept between 8 and 14 cm. of water. During the second hospital day, while on perfusion, the heart rate rose to 200 per minute, which was triggered by paroxysms of coughing. With the use of propranolol the rate was reduced to 120. Intermittent tachycardia of 160-180 persisted for 14 hours after perfusion. Bradycardia as low as 20 beats per minute was initiated by tracheal suctioning and coughing. This arrhythmia was corrected with atropine.

After 48 hours using 100% oxygen in the respirator and at a perfusion rate of 1.3 liters per minute, a second

Fig. 2—Circuitry of venoarterial perfusion.

venous catheter was added to increase the venous return. The second catheter doubled the venous return to 2.5 liters per minute. Concomitantly the respirator oxygen concentration was reduced to 80%, at which time the arterial oxygen tension was 48 mm.Hg. Twelve hours later the venoarterial perfusion was gradually reduced and terminated when it was possible to reduce the oxygen concentration in the respirator to 60%. At this point the arterial oxygen tension was 52 mm.Hg. The total perfusion time was 62 hours (Figure 3). Aqueous penicillin (12 million units daily), kanamycin (1 gm. daily), cephalothin (8 gm. daily) and chloramphenicol (2 gm. daily) were given until it was found that his sputum cultures were negative on the fourth day. On the eighth day purulent secretions from the trachea grew *Escherichia coli* and kanamycin (1 gm. daily) was reinstituted. This was later changed to gentamicin (240 mg. daily) when cultures grew *Pseudomonas aeruginosa*. Steroids were administered at this time when an allergic-type rash was observed. Gentamicin (240 mg. daily) was continued from the twelfth to seventeenth hospital day, at which time all antibiotics were discontinued.

In order to maintain an adequate hemoglobin level throughout the perfusion period it was necessary to transfuse 11 units of packed cells and four units of whole blood. The plasma hemoglobin reflected hemolysis due to pumping and oxygenating artificially. The maximum level reached was 15 mg.% at the fourth hour of perfusion and was 7.3 mg.% two hours after termination.

Fig. 3—Relationship of arterial oxygen tension to oxygen concentration in respirator and to flow rate through membrane oxygenator.

*This equipment was transported from St. Joseph's Hospital, St. Paul.

of perfusion. Platelet levels remained above 127,000 and rose to 706,000 nine days after the perfusion terminated. No platelet packs were required. Disseminated intravascular coagulopathy was not found. Fibrinogen levels remained normal. After fifteen days of antibiotics and starvation, bleeding from the trachea occurred and was corrected by Vitamin K therapy.

Significant azotemia was never encountered, even with marked precannulation anoxia. Periodic use of furosemide resulted in prompt urine production and reduction of the central venous pressure to normal levels. Oncotic pressure decrease associated with albumin drop of 3.2 gm.% to 1.8 gm.% on the eighth hospital day was corrected with a total of 300 cc. of salt-poor albumin on the tenth and eleventh hospital days. This prompted marked diuresis.

In order to control paroxysms of coughing daily doses of morphine sulfate (up to 280 mg.), diazepam (60 mg.), chlorpromazine (150 mg. daily), phenobarbital (720 mg. daily) and anectine (up to 250 mg. daily) were required.

He appeared occasionally to comprehend commands. He moved all four limbs. Generalized hyperreflexia with bilateral ankle clonus was present initially. He had pectoralis and masseter muscle twitching later in his hospital course. Serum calcium levels were 7.5 mg.% Intravenous calcium stopped the twitching. Later, calcium therapy was reinstituted as signs of impending tetany appeared. The electroencephalogram during the second hospital day showed diffuse irregular slowing without focal changes.

On the seventeenth hospital day withdrawal from the respirator and sedation were successful. The patient gradually awakened and the tracheostomy tube was removed on the twenty-fifth hospital day. When discharged on the thirty-seventh hospital day, the patient was fully conscious, alert and reacting appropriately. His weight was 115 pounds, 40 pounds less than his admission weight (Figure 4).

Discussion

Influenza has been known to appear in wave-like epidemics with excess deaths recorded, especially in 1918, 1951 and 1957.⁷ Eickhoff associated increased morbidity and mortality with individuals over 65 years, pregnancy or with a chronic disease process. The patient in this report was not in any of these groups, but he smoked one package of cigarettes daily for thirty years.

It is known that the Minneapolis area was the site of an epidemic during January and February 1972. Dr. Henry Bauer of the Minnesota State Department of Health recorded monthly influenza cases from November 1971 to April 1972, with peaks in January and February. Influenza deaths for this period went from seven in November to nine in December, 127 in January and 74 in February. Members of the patient's family were also affected by a "flu-like syndrome".

The decision to use the Membrane Oxygenator came when all other conservative measures failed to keep the arterial blood oxygen tension above 30 mm Hg. Early recognition of the deteriorating pulmonary state allowed sufficient time for preparation of the Membrane Oxygenator. Extracorporeal blood flow was increased from 1.3 liters to 2.6 per minute to allow the respirator oxygen concentration to be lowered from 100% to 60%.

Although venovenous perfusion has been described,⁴ and has the advantage of obviating an

Fig. 4—Upright postero-anterior chest film showing complete clearing of bilateral opacities ten weeks after perfusion.

arterial cannulation, veno-arterial perfusion was used here because it offered a way to perfuse the brain and coronaries with adequately oxygenated blood. It also excluded the lungs from further trauma by particulate emboli which would be filtered out in the lungs by venovenous perfusion. By using the saphenous route to the iliac veins rather than direct cannulation of the femoral veins the necessity of peripheral femoral cannulation to prevent edema was obviated. By using a small cannula distally and a larger one proximally in the axillary artery through one arteriotomy no ischemic changes were noted in the arm distally.

Heparin doses were held to a minimum 4000 units every four hours by adding only that amount of heparin to keep the Lee-White clotting time above 20 minutes. This entailed doing Lee-White times frequently during the 62 hours of perfusion.

Fluid retention was prevented by restricting the intravenous fluids to approximately 100 cc. per hour of 5% glucose in 0.2% saline. Circulating volume deficits manifested by low central venous pressure recordings and anemia evident by low hemoglobin and low hematocrit levels were corrected with 11 units of packed cells and four units of whole blood during the 62 hours of perfusion. The need for this quantity of blood has been previously observed.²

Although antibiotics were used initially, they were discontinued after cultures were negative.

Tracheobronchial superinfection, first with *Escherichia coli*, then *Pseudomonas aeruginosa*, appeared on the eighth and twelfth hospital days. The use of steroids initially and on the eighth day, following the allergic-type rash, may have encouraged this bacterial overgrowth.

Coughing spasms were a constant problem. Influenza leads to intensive mucosal inflammation and was thought to be the main cause for this symptom, especially after the pulmonary edema had decreased.

Influenza complement fixation pre- and post-convalescent titers were 1:64 three days after admission, increasing to 1:512 nine days later. This was considered diagnostic for Influenza-A infection. The patient experienced no respiratory symptoms following hospitalization. He has since returned to his work with no limitations.

Acknowledgments

Special recognition must be paid to the Intensive Care Unit and Operating Room nurses at Unity Hospital, without whose support this endeavor would not have been possible. Recognition also must go to Drs. Brian Campion, Arnold Lande, Irving Katz and Richard Johnson for consultation during the patient's illness. Twenty-four hour supervision of the perfusion was maintained by the cardiopulmonary pump team composed of Sister Victorine Long, M.S., R.M.T. and Thomas Golden, R.N. We also recognize Barbara Kennedy, R.R.A., Director of Medical Record Services, Unity Hospital, for her help in preparing this manuscript and bibliography.

Pseudotumor Cerebri

SIDNEY K. SHAPIRO, M.D.* and IRVING SHAPIRO, M.D.†

PATIENTS PRESENTING with increased intracranial pressure and papilledema present a diagnostic and therapeutic challenge. A rapid complete investigation to determine the cause of the increased intracranial pressure is essential. With increasing frequency, a condition called pseudotumor cerebri is being recognized. The diagnostic criteria for the diagnosis of pseudotumor cerebri are: (1) increased intracranial pressure with papilledema and headache, (2) normal ventricular system as demonstrated by ventriculography and/or pneumoencephalography, (3) increased spinal fluid pressure with a normal cell count and protein in the spinal fluid, (4) absence of other abnormal neurological signs with the exception of diplopia usually produced by one or both sixth nerve palsies and less frequently, by involvement of other cranial nerve palsies.

The electroencephalograms are usually normal except in cases secondary to trauma or infection. Brain scan studies are normal. Some definite causes for pseudotumor cerebri have been established. The Table tabulates the various etiologies of pseudotumor cerebri. After consideration of all known etiologic factors, there is a large group remaining comprising slightly more than one-half of the reported cases of unknown etiology. In this latter group, there is a peak incidence in the 4th decade. There is no history of infection or injury. The largest percentage of patients in this group are females and obesity is mentioned as a frequent clinical feature of the females in this group.

A patient who fulfills the criteria for the diagnosis of pseudotumor cerebri has been encountered and the detailed case report of this patient is felt to be of considerable interest. This patient has been followed by serial fundoscopic pictures to document her progress. The patient also serves to underline the difficulties encountered in the treatment of such a problem.

Case Report

A female patient, age 20, dated the onset of her symptoms to April 1, 1970. At that time, she developed some stiffness of the neck associated with some overhead work and this was followed by headaches, nausea, double vision and blurring of vision.

On examination with the exception of mild nuchal rigidity, the positive findings were restricted to the visual apparatus. The patient had a two to three diopter choke on the left side and a two diopter choke on the right side. There was tortuosity of the veins and slight hemorrhage. On visual field examination, there was barest suggestion of field depression on tangent screen but peripheral fields were entirely full and normal and the blind spots were bilaterally enlarged. There was no spontaneous diplopia noted but with red glass testing, diplopia was elicited in gaze up and to the left and there was noted a mild paresis of the left superior rectus muscle. This paresis was transient and clear within several days. The patient was obese. Routine Xrays of the chest, skull and brain scan and electroencephalogram performed April 6, 1970 all were within normal limits.

On April 10, 1970, bilateral cerebral angiography was performed and was entirely normal. On April 12, a spinal tap was performed. Spinal fluid pressure was 550 mm. with normal cell count and normal protein. On April 20, ventriculography was performed and was negative. On April 28, a pneumoencephalogram was performed and was entirely normal, with good filling of the ventricles and subarachnoid spaces. The medical

assessment of this patient was negative except for a uric acid of 10.

The patient was started initially on a program of fluid restriction and Osmoglyn six ounces every 12 hours. This was given over ice using a large straw and no fluids were given for three hours after each ingestion, with the fluids being restricted totally in a 24-hour period to 1000 cc. Dramamine 50 mg. by hypo was used every six hours as necessary for nausea. On May 11, the Osmoglyn was increased to three times a day. On May 18 the patient was put on a salt free diet and fluid intake was cut down to 700 cc. per day and 800 calorie diet started. In spite of these measures, the papilledema increased and the patient developed fresh hemorrhages in the eyes (See Figure 1). On May 22 Decadron 2 mg. three times a day by injection was commenced. Following this addition to the therapy, there was a gratifying improvement in the papilledema and it gradually decreased. Fresh hemorrhages no longer occurred and a repeat spinal tap on June 2 revealed that the pressure had dropped to 230 mm. of water. The Osmoglyn 6 oz. three times a day and the Decadron 2 mg. three times a day by mouth were continued on an outpatient basis. The patient received amphotoil 2 tbsp. three times a day. The patient gradually improved on this regime. The Decadron was gradually decreased to .5 mg. three times a day and on October 15, the Osmoglyn was discontinued. Decadron was gradually decreased to .5 mg. twice a day, commencing November 16 and on December 3, decreased to .5 mg. daily.

The patient while on Decadron developed an increasing hypertension with values reaching on March, 1, 1971 to 210/150. Decadron was discontinued on that date. The hypertension gradually subsided and a final evaluation of her eye problem revealed a complete resolution of the papilledema. When rechecked on June 17, the hyperemia and edema had cleared and the fundoscopic photos were normal (See Figure 2). Visual fields showed a normal outline and a normal blind spot. The patient was discharged from further neurological care having apparently made a complete recovery.

Discussion

The literature on this subject is confused by

Fig. 1—Papilledema due to pseudotumor cerebri.

the various names applied to the same condition. Pseudotumor, serous meningitis, serous arachnoiditis, chronic arachnoiditis, otic hydrocephalus, toxic hydrocephalus, and benign intracranial hypertension have been used as synonyms for pseudotumor cerebri.

Reviews by Davidoff,¹ Sahs and Joynt,² and Frenkel³ serve to outline the historical background and the problems encountered in the diagnosis of pseudotumor cerebri. Davidoff was able to report 89 cases which included 61 of his own which met the criteria for pseudotumor cerebri of unknown cause. He also reported on a number of cases preceded by ear and mastoid infection and other cases associated with infection or trauma elsewhere in the body.

In the patients comprising the Davidoff's experience in the group of no known etiology there were 18 females and 11 males. In three of the 18 women, unusual obesity was noted. In none was there an association with pregnancy or miscarriage. In the combined group of 89 cases, the frequency of females to males was two to one. Peak incidence was in the fourth decade. Sahs and Joynt² added to the literature cases of cerebral biopsy taken from patients with pseudotumor cerebri and were impressed with the profound swelling present in the material obtained from these cases. Ten such cases were studied and intracellular and extracellular edema was demonstrated. On occasion angiographic visualization of the superior longitudinal sinus is indicated if superior longitudinal sinus thrombosis or thrombosis of one of the lateral sinuses is suspected. Ray and Dunbar⁴ called attention to the observation that obstruction of the sagittal sinus alone or in con-

Fig. 2—Normal disc following response of pseudotumor cerebri to treatment.

junction with the transverse sinus or obstruction of both transverse sinuses with sparing of the sagittal sinus could produce an increase in intracranial pressure.

The treatment of pseudotumor cerebri requires individualization of treatment. As in our patient, salt reduction and the use of Osmoglyn should be attempted initially. If there is a failure to respond, the addition of Decadron may produce additional benefit and in many instances, this regime will cause a resolution of the papilledema and effect a cure. In a majority of instances, the threat to vision is not great and the treatment can be handled along the conservative lines as outlined in this patient. On occasion, it is necessary to resort to heroic measures such as subtemporal decom-

pression to save the vision. This procedure, however, is in itself not without some risk, as such intervention may precipitate an acute loss of vision according to Hollenhorst.⁵

In following the progress of treatment in this patient, repeated fundoscopic pictures were obtained and were of immeasurable value in documenting the patient's response to treatment. The most striking of the photographs have been reproduced (See Figure 1 and Figure 2). Figure 1 represents the papilledema at its maximum while Figure 2 shows the excellent result from treatment with the complete resolution of all fundoscopic pathology. This technique is recommended so as to document objectively the various stages of the papilledema encountered in this condition.

Annual Meeting Preparations Underway

John J. Regan, M.D., *President* of Minnesota State Medical Association announces the appointment of *Robert D. Semsch, M.D.* as Chairman of the Scientific Assembly Committee.

The Range Medical Society and St. Louis County Medical Society, the hosts for our 1974 annual meeting, have begun the task of planning the local arrangements for the Duluth meeting. Named to the Local Arrangements Committee are: *William Jacott, M.D.*, Chairman; *Franklin Johnson, M.D.*, Banquet, Hospitality, Transportation; *William Slack, M.D.*, Public Relations; *Donald VanRyzin, M.D.*, Registration and Reservations; *Thomas Stolee, M.D.* Scientific Exhibits; *Max H. Berns, M.D.*, Bridge Tournament; *Andrew Reardon, M.D.*, Golf Tournament; *Joseph Leek, M.D.*, Tennis Tournament.

Drs. Pearson and Schimelpfenig Honored at Medical Staff Meeting

Dr. Bror Pearson and Dr. Ted Schimelpfenig were honored at the September Medical Staff Meeting at St. Francis Hospital. Both physicians practiced in Shakopee and Chaska before St. Francis Hospital opened and have been affiliated with St. Francis Hospital Medical Staff for 35 years. An award of appreciation was presented to them for their outstanding contribution to St. Francis Hospital and for their loyalty and dedication in the service of the sick.

Surgical Treatment of Lung Cancer

Five-Year Follow-up of 266 Patients*

JOSIAH FULLER, M.D.†

WHEN THE OVERALL experience with a lethal disease is unfavorable, we tend to become so discouraged with the available treatment that we forget in selected cases lives can be saved. Carcinoma of the lung has such a reputation because statistics are compilations of an increasing number of deaths. A careful follow-up of many surgical series will show that early operations of bronchogenic carcinoma yield results that compare favorably with most internal cancers.

The following is a study of all patients with cancer of the lung who had a thoracotomy by the author from 1953 to 1966. There were 276 patients; 266 (96%) were followed for five years or to death and are the subject of this paper. This excellent follow-up is due to the persistence of the medical records personnel in the Duluth hospitals, the Duluth Clinic and the Duluth Tumor Registry. Survival rates shown are determined from the date of operation. All deaths, whether operative, postoperative or from any cause, were included.

The average age of the patients was 59 years, although 72% of the patients were in the sixth and seventh decades of life, three were in their thirties and one was 82 years old.

Seventy percent of the patients had a pulmonary resection for their carcinoma. As shown in Figure 1, 36% of the 187 patients lived for five years, while all patients who did not have a pulmonary resection were dead in less than three years. Pneumonectomy was done when necessary; more limited pulmonary resection was performed whenever it offered an adequate cancer operation because of the peripheral location and limited extent of the lesion. Operative mortality for the two procedures was comparable; 11% for pneu-

monectomy and 10% for lobectomy. Figure 2 indicates a five-year survival rate of 30% for patients who had pneumonectomies and 45% for those who had lobectomies or a lesser resection.

Forty seven of the 266 patients subjected to thoracotomy were female. This small group had a significantly better five-year survival; 43% contrasted with 25% for the entire group.

The histologic classification of cancer of the lung had significant clinical implications. As shown in Figure 3, the resectability rate of squamous cell carcinoma was 80%, adenocarcinoma

Fig. 1—Survival of resected cases compared with unresected.

Fig. 2—Survival of lobectomies compared with pneumonectomies.

Fig. 3—Influence of cell type on resectability.

Fig. 4—Influence of cell type on survival of resected cases.

Fig. 5—Influence of metastases to lymph nodes on survival rate of resected squamous cell carcinoma.

67% and alveolar cell carcinoma 100%. Figure 4 indicates a five-year survival for alveolar cell carcinoma patients of 75% while that for patients with squamous cell carcinoma and adenocarcinoma was 37% and 32% respectively.

Patients with small cell carcinomas had a resectability rate of 43% and only two patients lived five years after resection for small cell carcinoma. The diagnosis is always questioned when a patient with small cell carcinoma survives five years. This is the working diagnosis the surgeon was given at operation. The decision whether to operate upon or resect a small cell bronchogenic carcinoma should be based on the extent of the carcinoma. We should not be discouraged from operating, because of a biopsy report of small cell carcinoma for, as this group shows, we may be depriving that particular patient of his only chance for five-year survival.

Undifferentiated carcinoma was only slightly better than small cell carcinoma. Fifty-five percent of 51 patients had a pulmonary resection. Of these, five patients or 18% lived five years.

Seven patients had tumors which would not fit into the classification shown in Figure 4. Three patients had lobectomies for carcinoid tumors and lived five years. Another patient had a pneumonectomy and mediastinal lymph node dissection for an extensive carcinoid tumor and lived 1½ years. A lobectomy was done for a patient with a cylindroma of the bronchus and the patient lived five years. Two patients had sarcomas of the lung; one had a lobectomy and lived three and a half years and the other had a pneumonectomy for an angiosarcoma and died after two years.

The survival rate is significantly better for patients with most cancers when regional lymph nodes are not involved. This also occurred with bronchogenic carcinoma. The five-year survival rate for 36 patients with squamous cell carcinoma with metastases to the lymph nodes was 22% while patients with squamous cell carcinoma with negative lymph nodes had a five-year survival rate of 47% (Figure 5).

Exploratory thoracotomy may be a big operation when nothing surgically can be done. Four percent of the patients who had an inoperable carcinoma found at thoracotomy expired post-operatively. The author believes that the 30% unresectability rate shown in Figure 1 for patients subjected to exploratory thoracotomy is high. For

this reason, I now do an anterior mediastinotomy as described by McNeal and Chamberlain¹ when a lesion might be unresectable. This is a better operation than mediastinoscopy because it allows adequate exploration of the mediastinum to determine operability yet is much less traumatic than thoracotomy. In a recent series of 57 patients, 20 (35%) were unresectable on the basis of anterior mediastinotomy. These patients did not require thoracotomy.

Summary and Conclusions

Of 266 patients who were subjected to thorac-

otomy for cancer of the lung, 25% lived five years; 36% of 187 who had a pulmonary resection lived five years. Of 53 patients with bronchogenic squamous cell carcinoma without metastases to lymph nodes, 47% lived five years.

Although results of surgical treatment of most cancers have a substantial potential for improvement, undue pessimism regarding surgical treatment of cancer of the lung may delay early surgical care and be a real disservice to the patient with this disease.

Cover Photo

"Nicollet at Christmas"

Dr. Reinhold O. Goehl, Jr. and his wife were having dinner at Daytons with their three daughters several years back when the idea came to snap the cover photo. A Nikon F Camera with a 50 mm lens was used. Dr. Goehl told the Editors he always carries his camera with him as one never knows when an opportunity to snap the unusual might occur. Besides his interest in still life photography, he enjoys taking shots of his family and Minnesota's great outdoors.

A native of Grand Forks, North Dakota, and a graduate of the University of Pennsylvania Medical School, Dr. Goehl began his OB-GYN practice in Minneapolis in 1968. He is a Diplomate of the National Board of Medical Examiners and certified by the American Board of Obstetrics and Gynecology in addition to being a Fellow of the American College of Obstetricians and Gynecologists.

Oliver H. Beahrs, M. D.

Dr. Oliver H. Beahrs, a surgeon at the Mayo Clinic, Rochester, Minnesota, has been elected to serve on the nine-man Board of Trustees of the American Association of Medical Clinics.

The American Association of Medical Clinics, which is the national association representing group practice and group practice physicians, includes in its membership nearly 350 medical clinics and their 12,000 affiliate physicians throughout the United States and Canada.

Osteoporosis

A Six Months Experience At Saint Mary's Hospital, Minneapolis

ROBERT L. WONSAVAGE, M.D.*

THE ROLE OF PRIMARY Idiopathic Osteoporosis as a cause of disability and pain in the elderly is well known. Osteoporosis is a common radiologic finding. Back pain, kyphosis and scoliosis are frequent findings in the elderly osteoporotic. The treatment is largely symptomatic and the physiology of the disorder incompletely understood. The true incidence of the disease in the population is probably unknown and most reports are incomplete, segmental and skewed. It is generally felt that the incidence increases with age and approaches a figure of 25 to 50 cases per 100 persons over the age of 70.

The present study examines the consistency of the above in an unselected series of admissions to Saint Mary's Hospital. Saint Mary's Hospital is a medium sized community hospital that offers a wide variety of services to its patient population and no one subset of patients or medical practice is over represented. A patient profile was constructed and clinical, laboratory, radiologic and therapeutic parameters examined. Success in diagnosis of Osteoporosis was evaluated utilizing the Observed to Expected ratio.

Materials and Methods

This was a retrospective analysis of all primary and secondary diagnoses of Osteoporosis at Saint Mary's Hospital during the first six months of 1971. All data generated are derived from the clinical records of the 25 patients diagnosed as osteoporotic for that period.

Information such as age, sex, height, weight, laboratory studies and findings were merely recorded as such. Simple statistical analysis to determine mean values and/or percent of patients with a given result or study were compiled in the usual manner.

Examining historical data several arbitrary criteria were established in assessing whether a pa-

tient had a history and/or physical findings suggestive of Osteoporosis. A history was deemed suggestive if any of the following were present: back pain, other skeletal pain, known diagnosis of Osteoporosis, multiple fractures in the past or recent fall with back or other pain. Physical exam was considered suggestive if mention was made of pain elicited over or along side of the spine or other boney areas, or associated muscle spasm noted, or if fracture (other than compression fracture) was present.

All chest films were reviewed by a radiologist and initial and final interpretations compared for concordance.

In evaluating therapy, patients were divided into two categories; those who received no therapy for their Osteoporosis and the remainder who received any. With respect to physical therapy no special analysis of the modalities employed was attempted only whether or not the patient received such therapy.

In looking at incidence it was necessary to average figures from several sources to arrive at a new incidence for each age category.¹⁻³ Undoubtedly these figures were incomplete and artificial but served for the purpose of this study as a range. Moreover, it allowed us to examine our own age specific incidence and estimate our skill or lack of same with this diagnosis.

Results

PAS Charts

Utilizing the hospitals Professional Activity Study Charts, 27 diagnoses of osteoporosis were found at Saint Mary's Hospital for the first six months of 1971. These 27 diagnoses reflect 27 hospitalizations for 25 patients. The Professional Activity Study charts listed nine as primary and 18 as secondary diagnoses. Upon close review of these charts 14 primary and only 13 secondary diagnoses were found. The confusion stems from the practice of recording various fractures as diag-

*St. Mary's Hospital, Minneapolis, Minnesota.

noses separate from osteoporosis, in those instances where the former were secondary. All 25 patients had Primary Idiopathic Osteoporosis.

Patient Profile

Primary Idiopathic Osteoporosis is primarily a disease of the aged. In the present study no patient younger than 50 years of age was found and only three in the 50 to 59 year range (Table 1). Our youngest patient was 56 and our oldest 91. The mean age in our patients was 68.

TABLE 1
Age & Sex Distribution

Age	No.	F	M
< 50	0	0	0
50-59	3	3	0
60-69	6	4	2
70-79	5	5	0
80+	9	8	1

The majority of our patients were female (22 of 25). Because of the abundance of females and the supposed importance of estrogen in this disease, an attempt was made to look at parity; unfortunately, data on parity was available for only four of 22 women (18%), and no useful analysis could be made.

Weight and height data were available for 44% and 40% of the patients respectively. The mean height of these people was approximately 64 inches, and their mean weight was 139 pounds. Two patients weighed more than 200 pounds, totally deleting them did not appreciably change mean weight.

It would thus seem that we might adopt the ever popular little old lady as our typical osteoporotic patient.

Historical and Physical Findings

Histories and physical examinations were done on all of these patients. On close review of these histories and physicals it was found that 88% of the patients had a history suggestive for Osteoporosis. The commonest complaint was low back pain frequently of long duration (Table 2). Interestingly, only 41% of the physical exams mentioned findings suggestive of osteoporosis; chiefly spinal and para spinal tenderness and muscle spasm. This may mean one of several things: examination was incomplete, suggestive findings were ignored, or a significant number of the patients were either malingering or extremely stoic

and non communicative. It is of further interest that kyphosis or scoliosis or both were found in 64% of the patients. All 16 patients with this finding were properly identified radiologically, only five of 16 were identified on physical exam. It seems apparent that with kyphosis or scoliosis as one of the sole physical abnormalities seen in a large percentage of osteoporotics, it should be searched for vigorously on examination. Indeed this parameter may be a significant indicator or predictor of Osteoporosis in the asymptomatic patient.

Multiple fractures past	3
Recent fall	3

Laboratory Findings

Of the patients studied 100% had had a CBC, UA, serum Ca and Bun. The first two studies reflect a routine that applies to practically every hospitalized patient at Saint Mary's. The latter two may reflect the utilization of a chemistry screening profile rather than a well thought out evaluation of a specific disease entity.

In 70% of the patients a determination of the ESR was made, in 33% thyroid function was evaluated with a variety of tests. Nineteen percent of our population had alkaline phosphatase and 11% serum phosphorus determinations.

In no patient was acid phosphatase, serum creatinine, urinary steroid excretion or vitamin D absorption study done. Among a variety of other laboratory studies only the serum protein electrophoresis was done with any frequency. Forty-one percent of the patients had ELP's, properly reflecting the need to rule out multiple myeloma; all the studies were normal.

Of all the laboratory work done little was found that was consistently abnormal, except for the erythrocyte sedimentation rate and the urinalysis. Eighteen of 19 sediment rates were elevated with a mean of 33 and a range of 17 to 54. Fifteen urinalyses were positive with respect to microscopic findings of hematuria or pyuria, two patients had minimal proteinuria and only one culture proven urinary tract infection was found. Four determinations of blood urea nitrogen were elevated minimally in the 20 to 30 range. Three

patients had mild leukopenia and one a leukocytosis. A single abnormal EMG was recorded.

Radiologic Findings

A most important tool in the diagnosis of Osteoporosis is the Xray, and spinal films are usually indicated. Eighty percent of our patients had spinal films of one sort or another, and in all cases when they were done they were positive. Seventeen lumbar, ten thoracic and six cervical films were obtained. Lumbar films would seem to be the study of choice for screening, especially since only 10% (three of 29) of chest films were read as indicative of Osteoporosis. Twenty percent of these patients had no chest Xray. A variety of other films were done with variable results, only films of the pelvis were consistently positive in these patients (seven of seven).

In further evaluation of the chest Xray as a diagnostic tool in Osteoporosis, a small study was undertaken. Of the original 20 posteroanterior chest films three (10%) were felt to indicate osteoporosis. In all three cases two or three chest films had been done, yet another patient with four films had none that were positive. These 29 films were coded numerically and read by one of the radiologists at Saint Mary's. The question posed was "which of the following films meets your criteria for the diagnosis of Osteoporosis." Seven films (24%) met these criteria for osteoporosis. On breaking the numerical code concordance between original and present readings was zero (Table 3), and there was no overlap as regards positivity or negativity on first and second readings.

TABLE 3
Radiographic Readings

First		Second			
1st	+	3	2nd	+	7
2nd	+	0	1st	+	0
2nd	-	3	1st	-	7

Allowing for the fact that the study was small, the number of readings inadequate and the approach biased, several things are apparent. While it still seems that posteroanterior chest films are not good screening studies, one might expect a positive report between 10 and 34% of the time. This was not achieved. Perhaps the addition of lateral films would increase the pickup of osteoporosis and finally, with the diagnosis under consideration more films may be read as osteoporotic.

Hospital Stay

The mean hospital stay was 16 days with a

range of three to 65. The time necessary for recovery from an acute injury in a patient with osteoporosis is estimated at three to four weeks on the average. In this time most patients not seriously injured should be able to return to a former or near former level of activity and self care. Of course the severity of the patient's injury and the presence or absence of other disease will determine actual length of stay. It is difficult to state what the average stay for osteoporosis should be, but looking at those with a primary diagnosis of osteoporosis, the mean stay was only 11 days, which may be somewhat short. Intensive medical care is only needed in a small number of these patients, and many could spend the majority of their hospitalization in an extended care facility.

Therapy

In evaluation of the treatment these 25 patients received, the following was found: five (20%) received essentially no specific therapy, two of these were instructed to lose weight; one was given a low calorie diet. Of the remaining 20 patients the following therapeutic approaches were used: 60% received physical therapy for variable lengths of time, 50% calcium supplementation, 30% multi-vitamins, 50% received hormonal supplementation (estrogen and/or androgen, two on thyroid), 20% were fitted or refitted for a brace. No one utilized phosphorus supplementation or suggested the use of bed boards. Finally, 13 of 20 were treated with a variety of analgesics and anti-inflammatory agents. Only two of 20 were treated with a combination of calcium, vitamins, hormones and analgesics. Due to the design of this study there was no way to analyze the effectiveness of any of the therapy used. No attempt to utilize newer therapies was made.

Hospital Population and Incidence Study

Primary idiopathic osteoporosis is uncommon before the age of 50. In the sixth decade the incidence rises sharply for women. Approximately

TABLE 4
Incidence Osteoporosis*

Age	% F	% M

80+	40	28

*Combined and averaged data (Smith, Gugenheim & Harrison)
Total admissions St.M.H. first 6 months 1971: 9316

20% of women aged 50 have osteoporosis as compared to 5% of the males. By age 70 the percentages are 30% and 20% respectively, and in the eighth decade the incidence is equal. Good data on actual incidence of osteoporosis is not easily available, but utilizing common estimates of incidence and comparing them with the incidence as determined in other studies¹⁻³ one can arrive at an approximation of the incidence of osteoporosis in each category (Table 4). These figures are probably somewhat conservative, since they reflect a mean of several values or the lowest estimate of incidence available. Comparing then the number of expected cases to the number of observed cases in each age-sex category and examining the observed-expected ratio it becomes apparent that osteoporosis is not being diagnosed in the frequency expected (Table 5).

Even assuming that our estimates of incidence and expected cases are grossly in error, and then reducing the number of expected cases by 90% the observed/expected ratios still fall far short of unity (Table 5).

- hanced.
5. The therapeutic approaches were so varied that they were not evaluable, but perhaps reflect the prevailing therapeutic confusion with respect to this entity.
6. Further, it was found that the only consistent clinical finding in a large number of patients was spinal deformity; the only consistent laboratory abnormality was an elevated ESR—a highly nonspecific test; and lastly, spinal films, especially lumbar films, were essentially diagnostic in and of themselves. The only consistent historical datum was back pain.
7. The entity primary idiopathic osteoporosis was probably underdiagnosed.
8. (a) While in each case analyzed there was sufficient evidence to suggest the diagnosis of primary idiopathic osteoporosis (namely diminished bone density on Xray), other common characteristics of this disease emerged. From this study it appears that the diagnosis is suggested in a female patient in the seventh decade

*O/E if incidence and expected 90% wrong.

Summary

1. Specific discrepancies were found between historical complaints of back pain and suggestive physical findings, between radiologic and clinical determination of spinal deformity.
2. Charts were incomplete with respect to data on parity, height, and weight.
3. Laboratory data base was deficient with respect to phosphorus, acid and alkaline phosphatase, creatinine, steroid excretion and vitamin D absorption studies.
4. Posteroanterior chest films were useless in screening for osteoporosis, but with consideration of the diagnosis their value may be en-

presents with a history of back pain and a finding of spinal deformity. The diagnosis is further strengthened if she is short and relatively light weight and if the laboratory is negative with the exception of a moderately elevated ESR. Final confirmation rests with spinal Xrays demonstrating diminished radiodensity.

- (b) These criteria may not be completely valid when applied to a larger population. Examining a larger population may not only refine but further expand these criteria and make early diagnosis of Primary Idiopathic Osteoporosis a reality.

Meconium Aspiration in the Newborn

MARTHA BURKE-STRICKLAND, M.D.* and NANCY B. EDWARDS, M.D.†

THE BABY WITH meconium in the amniotic fluid is known to be at risk.¹⁻⁵ Syndromes produced by aspiration of meconium by the fetus or newborn are quite variable in severity. Since the majority are reported to be mild and transitory,^{6,7} an attitude of complacency regarding the meconium stained infant often prevails until increasing tachypnea, grunting, and cyanosis a few hours after birth indicate that a serious problem is underway. Personal experience in a referral newborn intensive care unit paralleled that of Kachaner et al, who, in reporting on infants with aspiration syndrome transferred to their intensive care unit, noted a mortality rate of 15% among infants with meconium stained amniotic fluid and 35% among those found to have meconium in the trachea at birth. These authors suggested that more aggressive management should reduce morbidity and mortality of these infants.⁸

This is a report of a two year experience in trying to identify and aggressively treat in the delivery room the infant at risk from aspiration of meco-

nium.

Subjects and Methods

The 101 infants reported were born on the obstetrical service of Hennepin County General Hospital from January 1970 through December, 1971. Fetal monitoring was part of the intensive obstetrical care given high risk deliveries on the service. A fetus was considered at risk if meconium staining of the amniotic fluid was seen at amnioscopy or at rupture of the membranes. A pediatric team was available for care of the infant at delivery. Appropriate measures were taken to avoid chill stress during resuscitation and supportive oxygen and ventilation assistance were given when indicated by cyanosis or poor respiratory effort of the infant.

If meconium stained material was suctioned from the oropharynx, a decision was made whether to intubate the infant and whether to lavage the trachea with saline. Technique for lavage of the trachea has been reported previously.⁹

The infants fell into three main groups according to presence or absence of meconium in the airway (Table 1). Group I included infants who did not have meconium in the oropharynx at initial suctioning and, therefore, were not intubated

TABLE 1
Summary of Data Related to Meconium in the Airway and Method of Clearance of the Airway of 101 Infants with Meconium Stained Amniotic Fluid at Birth

() number who had respiratory distress.

or lavaged. Group II included infants who were intubated because of meconium in the oropharynx but were found to have no meconium in the trachea. Group III were infants who had meconium stained material suctioned from the trachea at intubation. Some of the intubated infants had suction only to clear the airway (No L), some had suction and lavage immediately at birth (Imm L), and in some, intubation and lavage were delayed 20 minutes or more after birth (DL).

At least one chest X-ray was obtained in 100 infants. In nine cases, X-rays were obtained before and after tracheal lavage. X-ray interpretation was based upon radiological patterns in neonatal aspiration syndrome described by Peterson and Pendleton.¹⁰ X-rays were rated as clear if both heart borders were sharp, no air bronchograms were present, and no linear or flocculent densities were seen in peripheral lung fields. A mild to moderate rating included faint air bronchograms beyond hilar areas with fine linear densities fanning out to the periphery or scattered small areas of nodular densities. Severe involvement included generalized nodular or flocculent densities, obscured heart borders, air bronchograms and focal areas of hyperaeration or complete opacification of the chest X-ray.

A resting respiratory rate of greater than 60 per minute, retracting, or grunting was counted as respiratory distress. In calculating average days of respiratory distress, only infants who had distress beyond delivery room resuscitation were counted.

Cultures were taken and antibiotics given initially at the discretion of house staff. Aqueous sodium penicillin 75,000 units/kg. and kanamycin 15 mg./kg. were used unless change was dictated by clinical course or results of cultures.

Apgar scores were defined as "low" if the score at either one minute or five minutes was

four or less and "high" if both the one minute and five minute scores were five or more.

In considering effects of gestational age, the infants were grouped according to gestational age of 38 weeks or less, 39-40 weeks, 41-42 weeks, and 43 weeks or more.

For infants of 38 weeks or less gestational age, hospital stay was adjusted by subtracting from the total hospital stay that number of days that would have been required for the infant to reach 2500 grams if he had gained 20 grams per day.

Outcome of the infants as measured by average days of respiratory distress and average day of hospital stay was correlated with Apgar score (Table 2), gestational age (Table 3), chest X-ray (Table 4), antibiotic therapy (Table 5), and method of airway clearance (Table 1).

Results

Of the 101 infants who had meconium staining of the amniotic fluid, 84 also had meconium stained material in the oropharynx. Sixty percent (50 of 84) of these had meconium stained material in the trachea (MIT). Occurrence of meconium in the trachea was not related to age of the mother, gestational age or sex of the infant. While some complication of labor or delivery was present for 80 infants and multiple problems were present for 36, only in toxemia (five or six) and breech position (seven of seven) did clinical background appear to have any value in predicting presence of meconium in the trachea.

Apgar Scores

Though there was a definite correlation between low Apgar scores and presence of meconium in the trachea ($p = <0.01$) a high score did not rule out MIT or subsequent respiratory distress. Infants with low Apgar Scores had longer hospital stays (Table 2).

Gestational Age

Apgar scores, chest X-rays, and adjusted hospital

TABLE 2
Relationship of Apgar Scores to Outcome of 101 Infants with Meconium Staining of Amniotic Fluid

() number who had respiratory distress

stay did not differ according to gestational age. The infant of 38 weeks or less was more likely to have positive cultures ($p = <0.001$) and longer periods of respiratory distress ($p = <0.05$) than term or post term infants. There was no difference in occurrence of MIT among infants of different gestational ages (Table 3).

Xrays

The infant with meconium in the amniotic fluid was more likely to have severe findings on chest Xray if he also had a low Apgar score ($p = <0.05$) or meconium in the trachea ($p = <0.02$) (Table 1). Infants with a clear chest Xray had less respiratory distress and shorter hospital stays than infants with severe x-ray findings ($p = <0.05$) (Table 4). In nine patients who had Xrays before and after tracheal lavage, there did not seem to be any worsening of the Xray in these cases and, in seven of nine, there was improvement. Lavage did not seem to be responsible for the severe x-ray findings.

Antibiotics

Antibiotic administration was associated with longer periods of respiratory distress and hospital stay. This appeared to be a function of initial condition of the infant influencing the decision to give antibiotics rather than an effect of antibiotics (Table 5).

Method of Airway Clearance

Respiratory distress occurred just as often and the period of distress tended to be longer in infants who had suction of the oropharynx only as it did in those who were intubated.

If no meconium was present in the trachea, there was no difference in respiratory distress regardless of timing or method of clearance of the airway. If meconium was present in the trachea, the period of respiratory distress was shorter if the infant was intubated, suctioned, and lavaged immediately ($p = <0.001$).

In five cases adequate respirations were established in the delivery room when the infant was

() number who had respiratory distress.

lavaged after intubation and suctioning alone had failed to achieve desired results. In each instance the resuscitating physician noted removal of thick tenacious mucous plugs.

Average length of hospital stay was longer for infants not intubated at all, infants who had delayed clearing of the airway, and those who had low Apgar Scores. For infants with no meconium in the trachea who had high Apgar scores, timing and method of airway clearance did not make any difference in hospital stay. For those infants with no meconium in the trachea but low Apgar scores and all the infants with MIT regardless of Apgar score, the infant had a shorter hospital stay if the trachea was intubated, suctioned, and lavaged immediately at birth. ($p = <0.05$).

Mechanical Complications of Intubation

Only one infant had stridor. This occurred in an infant who had traumatic intubation. Pneumothorax occurred as frequently in those not intubated as in those intubated (Table I). While bradycardia frequently was relieved by intubation and institution of ventilation, no bradycardia secondary to the procedure of intubation was noted.

Deaths

One death occurred in a term infant delivered by emergency C-section for uterine rupture. The infant had low Apgar scores, delayed clearance of meconium from the trachea and tension pneumothorax.

Discussion

Findings of this study indicate that, for infants with meconium staining of the amniotic fluid, the airway will not be adequately cleared by suctioning the oropharynx alone since fifty percent of the infants also had meconium stained material in the trachea. Morbidity as well as mortality appeared to be reduced by more aggressive clearance of the airway immediately at birth. In a recent investigation in which fetal monitoring and obstetrical management were thought to have influenced outcome favorably, Pakzad and Saling reported a death rate of 6.4% among infants

who passed meconium but had no other signs of fetal distress.¹¹ For this study the death rate was 0.99%. Reduction in morbidity was evidenced by shorter periods of respiratory distress and hospital stay found in those infants who were intubated and had the airway cleared promptly at birth compared with those who had delayed clearing of the trachea or suctioning of the oropharynx only.

There is a general reluctance to intubate newborns until after other methods of resuscitation have been tried. Part of this reluctance has stemmed from the high incidence of complications such as pneumothorax often associated with intubation of the infant. Evidence is accumulating that pneumothorax is more likely attributable to pathology that prompts the intubation rather than the intubation procedure itself.¹²

In this study, overall occurrence of pneumothorax was low (6%). Pneumothorax in the intubated infants (4.8%) did not differ significantly from occurrence of pneumothorax in non-intubated infants (11.6%). Nor was there any significant difference when pneumothorax of our intubated infants (two of 84) was compared with occurrence of pneumothorax in intubated infants investigated by Steele et al. (four of 50 infants).¹³ Though the numbers for our study were small, there was a significantly greater occurrence of pneumothorax in our non-intubated infants with meconium in the amniotic fluid (two of 17) than in the infants from routine vaginal deliveries reported by Steele (four of 300 infants) ($p = <0.01$). This suggests that, in infants with meconium in the amniotic fluid, pneumothorax is more likely associated with pathology present than the intubation procedure. These findings also suggest that the infant with meconium in the amniotic fluid is at risk from aspiration even if no meconium stained material is present in the oropharynx at initial suctioning. This concept is further supported by the longer periods of respiratory distress and hospital stay of the infants who had suctioning of the oropharynx only compared with those who were in-

() number who had respiratory distress.

tubated immediately.

The infants presumed to be at greatest risk from aspiration of meconium stained amniotic fluid were the infants who also had meconium in the trachea at birth. In these infants, prompt clearance of the airway was associated with significant reduction in respiratory distress and hospital stay compared with those who had delayed clearance of the airway. While evidence favored saline lavage as a valuable adjunct to suctioning in clearing the airway, the number of infants with MIT who received suctioning only was too small to permit valid comparisons with those who were suctioned and lavaged. Further work is needed to determine whether intubation and suctioning would suffice just as well as intubation, suctioning and lavage did in this study. Lewinski found that normal saline instillations did not produce inflammatory reactions in lungs of cats.¹⁴ Other studies

have indicated that the recommended technique of lavage does not compromise arterial blood gases.⁹ There was no evidence that any cases in this study were worsened by lavage and some appeared clinically or radiologically improved by the procedure.

It is unlikely that either suctioning or lavage will retrieve any debris already disseminated to the periphery of the lung. Therefore, it would seem advisable to take whatever measures are to be employed before the infant is stimulated to take deep breaths. It is concluded that the infant with meconium staining of amniotic fluid should be intubated immediately at birth for adequate clearing of the airway. Such intubation, carefully performed, should not increase risk for the infant and should improve the outcome. In addition, use of saline lavage to facilitate removal of debris from the trachea is not harmful and may be helpful.

It's The Law

No Liability for Diagnosis of Psychiatric, Not Somatic, Disorder

A patient was hospitalized for one week for diagnostic work-up because of a number of complaints and symptoms. The physicians concluded that none of the symptoms were organic and that she should seek psychiatric treatment. She then underwent a five week in-patient hospitalization at a neuropsychiatric center.

Three years later another doctor diagnosed chronic right maxillary sinusitis. Following surgery a pulmonary embolus was diagnosed and treated.

The patient contended that the doctors at the first hospital should have diagnosed at least a sinus condition and should have referred her for treatment for that at that time. The psychiatric hospital claimed that its doctors met the proper standards of care in handling the case and that indications of somatic disease were not present at that time.

The patient was denied damages by a California jury.

Immobilized Enzymes

Their Applications in Medicine

PAUL M. ANDERSON, Ph.D.* and WILMAR L. SALO, Ph.D.*

ENZYMES ARE USED routinely in many areas of clinical medicine. Their uses in the clinical laboratory as analytical reagents for measuring small amounts of constituents such as glucose or urea in blood and other biological fluids are well established. Measurement of specific enzyme activities such as serum transaminase and lactic acid dehydrogenase and isozyme patterns of the latter are valuable diagnostic tools. Enzymes are used in a more limited way as therapeutic agents; examples are the use of proteolytic enzymes to digest blood clots and the recent use of the enzyme asparaginase for treating patients with lymphocytic leukemia.

Considering the potential applications of enzymes in these and other areas of medicine their use has been limited. Many potentially useful enzymes (on the basis of their catalytic activities) are quite labile in solution in the purified state, and the preparation of purified enzymes in quantity by the usual procedures is expensive. Recent developments in enzyme technology involving procedures for the stabilization of enzymes by inclusion in or fixation on water-insoluble supports (immobilized enzymes) and the isolation of many enzymes in a highly purified state by the technique of affinity chromatography have demonstrated that the specific catalytic properties of enzymes will no doubt be exploited to a much greater degree in medicine and other fields in the future. The purpose of this article is to illustrate by selected examples some of the procedures employed and possible applications of these techniques in medicine.

Immobilized Enzymes

The majority of the techniques for immobilization of enzymes which have been published in the last few years involve the following types of interactions between the enzyme and an insoluble polymer:^{1,2}

1. Physical adsorption on the solid carrier by non-covalent interactions such as ionic binding to hydrophilic exchange resins.
2. Entrapment of the enzyme inside a polymeric gel. Entrapment occurs by polymerizing the gel in the presence of the enzyme. An important modification of this general procedure is the process of microencapsulation in which an enzyme solution is dispersed in an organic solvent and then polymerization is initiated so that a "gel" membrane is formed around the droplet.
3. Covalent chemical bonding of the enzyme to solid carriers such as porous glass, cellulose, Sepharose (a beaded form of agarose), or other synthetic organic carriers such as poly (ethylene-maleic anhydride). The reaction is usually carried out by converting the support to a reactive form which will react with functional groups on the enzyme which are not essential for catalytic activity (Figure 1).

No standard procedure is available for immobilization of an enzyme; the kind of reaction used in the coupling process and the support material used will depend on the properties of the enzyme and the purpose for immobilization. Obviously the conditions of the coupling process and the type

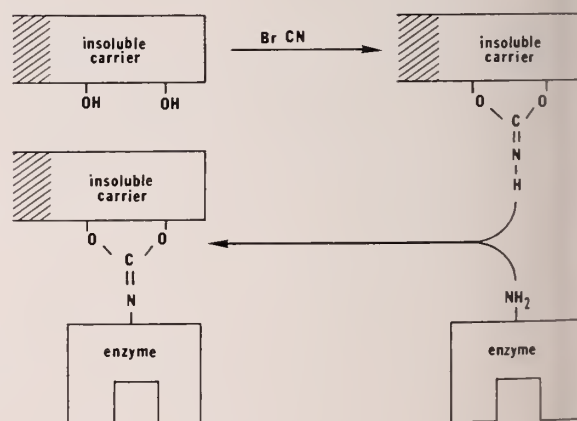

Fig. 1—Illustration of an immobilization procedure involving covalent attachment to an insoluble polysaccharide such as agarose. The polysaccharide is first "activated" by reaction with cyanogen bromide. The free amino groups of the enzyme or other soluble molecule are then reacted with the "activated" polysaccharide to give an insolubilized enzyme.

*School of Medicine, University of Minnesota, Duluth.

of reaction employed must be such that the structural properties of the enzyme essential for catalytic activity are not altered and access of the substrates to the catalytic sites of the enzyme are not hindered.

Immobilized enzymes have been found to be more stable than the corresponding soluble enzymes, although the catalytic activities are usually decreased. The immobilized enzymes can usually be used repeatedly thus reducing the need for expensive and constant purification of large quantities of an enzyme for use in a given process, such as, e.g., the conversion of benzylpenicillin to 6-aminopenicillanic acid by the enzyme penicillin amidase. Another advantage is that the enzyme can be removed from the reaction mixture by simply centrifuging or filtering, or the reaction mixture can simply be passed over the immobilized enzyme, e.g., through a column containing the supported enzyme; in either case the reaction product is then free from protein impurities which could lead to allergic reactions if the product was destined for therapeutic use.

A few examples of the applications of immobilized enzymes in medicine will be mentioned here; more extensive reviews of their general use have been published elsewhere.¹⁻³ The applicability of immobilized derivatives of urease and urate oxidase for the continuous and automated analysis of urea and uric acid was demonstrated by Hornby and coworkers.⁴ In their procedure the sample with appropriate additions to the flow stream is pumped through nylon tubes or powders containing bound enzyme and the products of the reaction are measured by mixing with appropriate reagents which react with the products to give a color which is measured by a spectrophotometer inserted in the line. The enzymes retained activity over a long period of time (four months involving 400 analyses in the case of urease) and the results were very reproducible. Similar procedures have been published for the use of glucose oxidase, peroxidase, and some dehydrogenases for analytical purposes in the clinical laboratory.

A very promising application of immobilized enzymes is their use in conjunction with an electrochemical probe (enzyme electrodes).⁵ An electrode specific for L-amino acids was prepared by covering a cation sensitive glass electrode with a gel containing the enzyme L-amino acid oxidase which catalyzes the following reaction :

The cation electrode detects the ammonium ions produced when an amino acid is present, the steady state potential of which is proportional to the ammonium ion concentration in the enzyme layer and, therefore, to the concentration of amino acid(s) in the solution. An electrode for measuring urea by a similar procedure employing urease has also been described; again, the cation electrode detects ammonium ions produced from urea by the following urease catalyzed reaction:

In both of these examples recently developed electrodes specific for ammonium ions could be substituted for the cation sensitive electrode and the CO₂ electrode could also be used with urease.

Asparaginase has been immobilized by covalent attachment to nylon tubing and the resulting immobilized enzyme has been shown to be effective in clearing *L-asparagine* from human blood⁶. Previous studies had shown that microencapsulated *L-asparaginase* injected into the peritoneal cavity or incorporated in an extracorporeal shunt through which the blood could flow was even more effective than the free enzyme in retarding the appearance of lymphosarcoma in mice implanted with lymphosarcoma cells. Although *L-asparaginase* has been shown to be useful in the therapy of acute lymphocytic leukemia in humans, the enzyme, which is isolated from *Escherichia coli*, has undesirable immunogenic side effects, has a short half-life in the plasma due to antibody production, and is prohibitively expensive. The possibility of using asparaginase immobilized to nylon as indicated above in extracorporeal shunts for removal of asparagine from the blood of patients with leukemia is currently being investigated and could eliminate some of these problems.⁶

Immobilized enzymes will very likely be applied in the future to the treatment of enzyme deficiency diseases. Acatasia is the result of a deficiency of the enzyme catalase in human tissues. Mice deficient in catalase die when treated with sodium

perborate but similar mice treated by injections of catalase or with extracorporeal shunts containing microencapsulated catalase are able to detoxify the perborate.⁷ This experimental work with mice suggests that similar procedures as illustrated in Figure 2 might be applicable to humans who suffer from this disease.

Various deficiency diseases related to the digestive process may be very accessible to corrective treatment with immobilized enzymes. Two such deficiency diseases are sucrose intolerance and isomaltose intolerance.⁸ Both of these diseases are digestive disorders and while they can be treated by the avoidance of sucrose and starch, respectively, a possible corrective treatment using immobilized enzymes would enable these individuals to lead a more normal life relative to their diet. This would require the preparation of appropriately immobilized enzymes which would then be ingested with each meal. For example, sucrose could be immobilized on Sepharose beads which could then be encapsulated within a semi-

permeable membrane; immobilization would stabilize the sucrose and encapsulation would protect it from proteolytic action.

Other applications of immobilized enzymes include their use in catalyzing transformations leading to medicinals or synthesis of medicinals (e.g., hydrolysis of benzylpenicillin as mentioned above and the synthesis of poly-I:C, a synthetic ribonucleic acid polymer which is effective in inducing interferon), as models of membranes and metabolic cycles in basic research (in a sense any biological system can be considered as one grand immobilized enzyme system!), and as immuno-adsorbents for the isolation of antibodies to the enzyme (or any antigen).

Affinity Chromatography

The numerous applications in medicine of immuno-adsorbents (immobilized antibodies or antigens) in medicine are discussed in the excellent review by Boguslaski et al.³ The technique of affinity chromatography for the purification of enzymes evolved from the demonstration that specific antibodies could be isolated by passage through a column containing antigen immobilized to a solid support.^{2,9} Purification was achieved because only the desired antibody had a specific and high affinity for the immobilized antigen. All the other proteins (and antibodies) were unretarded and passed through the column; the bound antibody could then be eluted from the column by changing the pH or other appropriate property of the eluting buffer. A characteristic of most enzymes is that they bind to their substrates or substrate analogues specifically and reversibly. The technique of affinity chromatography as applied to enzyme isolation (illustrated in Figure 3) involves selective adsorption of the enzyme to suitable insolubilized molecules (ligands) which can bind specifically to the enzyme (inhibitors, substrates or substrate analogues, antibodies, etc.). The great advantage of this procedure is that it exploits those properties of the enzyme which are its essential characteristics, i.e., the specificity and the physical and chemical behavior of the active sites of the enzyme. Most modern methods of enzyme isolation and purification (fractionation, chromatographic, and electrophoretic procedures) are general but non-specific techniques which permit separations on the basis of differences in protein properties such as solubility, charge, size, and shape and many steps resulting in low yields

Fig. 2—Two types of shunt devices with possible applications to an enzyme deficient disease such as acatalasia. a) The immobilized catalase is separated from the blood by a selectively permeable membrane (perhaps teflon) which allows H_2O_2 to enter. If the purified enzyme is stable immobilization may be necessary since the membrane would retain it. b) The catalase is immobilized on the walls of the shunt tube (perhaps nylon) and the enzyme comes in direct contact with the blood.

are often involved in the purification process.

Several extensive reviews have been published describing the methodology and applications of affinity chromatography.^{3,9,10,11} As with immobilized enzymes a standard procedure applicable to all situations is not available, although some general guidelines have evolved as a result of the numerous studies carried out in this area. The insoluble carrier must be inert, must be porous to permit penetration of the macro-molecules into the matrix and to permit a good flow rate, must be chemically and physically stable, and must contain sufficient and appropriate functional groups to permit attachment of a reasonably large number of ligands under mild conditions. It has been found that best results are obtained when the ligand is not attached directly to the carrier, but

rather to one end of a hydrocarbon chain ("arm") which is attached to the carrier; presumably when the ligand is attached close to the insoluble matrix the large enzyme cannot bind to it because of steric hindrance. The attachment of a ligand to the carrier usually involves modification of the ligand so that it will have a proper functional group which can be used for linking the ligand to the carrier. The ligand after modification should have a high affinity for the enzyme; preliminary specificity studies should be carried out to be certain that these alterations in structure involved in attaching the ligand do not substantially alter the affinity of the ligand for the enzyme. Adsorption of the enzyme to the insoluble ligand is usually carried out under conditions where the ligand-enzyme complex is known to be the most stable.

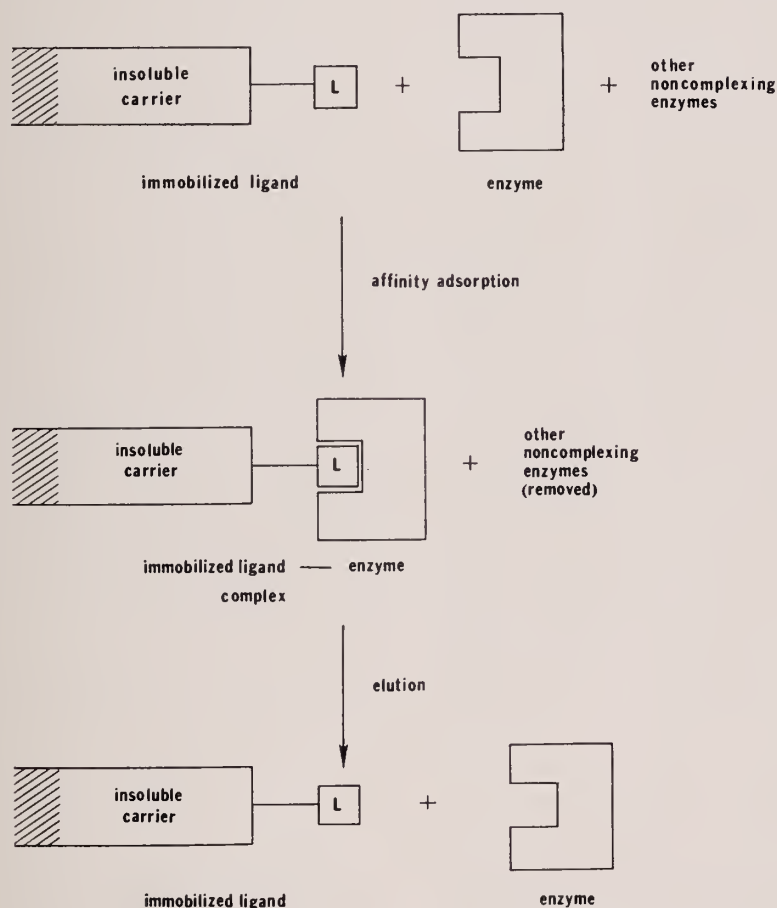

Fig. 3—General scheme illustrating the technique of affinity chromatography. Ligand (L) is attached to an insoluble carrier thus immobilizing the ligand. An enzyme or other biological molecule (hormone, antigen, antibody, or receptor protein, e.g.) having a specific binding site of high affinity for the ligand will bind to the immobilized ligand to form an immobilized ligand-enzyme complex. All other enzymes and other molecules not possessing a ligand-specific site are washed away leaving the one specific enzyme bound to the insoluble carrier. The bound enzyme is subsequently eluted from the carrier.

The enzyme is eluted (after washing away all unbound protein) by changing these conditions (pH, temperature, buffer, etc.) or in many cases by simply adding soluble ligand in high concentration to the eluting buffer which competes with and replaces the insoluble ligand.

Enzymes applied intravenously for therapeutic uses must usually be extremely pure to minimize undesirable immunological defense reactions and are, consequently, very expensive. An example of the successful application of affinity chromatography for the isolation of a therapeutic enzyme is the report that L-asparaginase can be isolated from extracts of *Escherichia coli* by chromatography on columns of ϵ -amino-caproyl-D-asparagine-agarose (ligand = D-asparagine; carrier = agarose; linking "arm" = ϵ -aminocaproic acid).¹² The enzyme was eluted from the column by addition of free D-asparagine and was obtained in higher purity and yield than the standard multi-stage procedure; in addition, the whole procedure was carried out in one step.

More recently Katz reported the isolation of human lysozyme by affinity chromatography on columns containing immobilized deaminated chitin from squid which has a very high affinity for lysozyme.¹³ The yields were in excess of 99% and the product, which was eluted from the column with acetic acid, was homogeneous and very active. Another advantage of the procedure is that the lysozyme can be isolated in just a few hours from a biological fluid such as human blood. The availability of reasonable quantities of human lysozyme offers the opportunity to explore many possible therapeutic applications for this enzyme. The enzyme splits the cell walls of bacteria causing lysis of the bacteria and has been shown to be effective as an antitumor agent, an antibacterial agent, and as a potentiator for many antibodies when it is administered as an antibiotic-lysozyme

complex. The use of human lysozyme therapeutically would minimize adverse immunological responses, although an immunological response which might result if lysozyme from another species was employed might not be a significant problem if immobilized lysozymes were used.

The general concept of affinity chromatography is not limited to the isolation of enzymes. In fact, it was first used, as indicated above, to isolate antibodies^{3,9} and with the increased use of radioimmunoassays the need for pure specific antibodies will increase and affinity chromatography will help meet this need. In this type of affinity chromatography the antigen (or hapten) is insolubilized by attachment to an appropriate support medium and the resulting immobilized antigen is used to purify the antibody as described above for enzymes. The procedure can be reversed and used to purify antigens; the antigen could be a hormone, enzyme, or other biological molecule. For example, rapid purification of human growth hormone might be accomplished in this way. Application to a problem of current research interest is the isolation and purification of "receptor proteins," whereby the effector molecule (such as a hormone) is immobilized and the bound "receptor proteins" eluted after washing away the unbound protein. Immobilized antigens have even been used to separate antibody-producing cells from other cells in this way.

The use of affinity chromatography is well established and will no doubt be applied to the isolation of even more enzymes in the future which were previously not available for exploitation as therapeutic or diagnostic agents. The field of immobilized enzymes is a new and very active area of research involving many disciplines and it can certainly be anticipated that new concepts of immobilization of enzymes and their applications to problems in medicine will be forthcoming.

Procainamide Hydrochloride Sensitivity

Manifested by Fever and Chills

MENACHEM S. SHAPIRO, M.D.*; ALAN TEITLER, M.D.† and DAVID GROB, M.D.*

PROCAINAMIDE HYDROCHLORIDE (P-amino-N-2 diethylaminoethyl) benzamide hydrochloride (Pronestyl®), has been widely used as an antiarrhythmic and antiarrhythmic agent. Hypersensitivity reaction to the drug has been uncommon, manifested as either a febrile reaction, usually with chills and sometimes with dermatitis, occurring after one to 15 days of drug administration,¹⁻⁶ or as a "lupus-like" syndrome, usually with fever, occurring after three weeks to 22 months of drug administration. In this report, a patient is described who developed fever, shaking chills, and dermatitis after 14 days of procainamide administration.

Case Report

Onset of Clinical Myocardial Infarction

The patient was a 61-year-old white man admitted to the Maimonides Medical Center with pain in his chest and left arm on May 14, 1967.

On the morning of admission, the patient developed weakness, diaphoresis, nausea and precordial pain which radiated to the left arm. He had had an episode of left hemiparesis seven years previously and was then informed that he had hypertension. There was no history of diabetes mellitus or of drug or food allergy. Three members of his immediate family had a history of myocardial infarction.

Physical Findings

Physical examination revealed blood pressure of 120/80 mm Hg. The pulse was regular at 96 beats per minute with occasional premature beats. The temperature was 98.2°F (all temperatures rectal). The patient was afebrile. His skin was cool and moist and there was slight peripheral cyanosis. Inspiratory moist rales were heard in both lung bases. The heart sounds were distant, and no murmurs were heard. The liver edge was palpated beneath the right costal margin. There was no dependent edema. The right carotid artery pulsation was slightly decreased. The deep tendon reflexes were increased in

the left lower extremity.

The admission hemoglobin was 16.4 gm/100 cc; hematocrit, 48 percent; white blood count, 22,900/cu mm with 83 segmented neutrophils, seven band forms, and 10 lymphocytes. The urinalysis was normal. The blood urea nitrogen was 25 mg percent, the creatinine 0.8 mg percent, serum glutamic oxalic transaminase 129 units, serum glutamic pyruvic transaminase 30 units, and lactic dehydrogenase 2000 units.

The Evaluation of Sensitivity

The electrocardiogram showed an acute inferior wall myocardial infarction and frequent runs of ventricular tachycardia. The patient was treated initially with intravenous diphenylhydantoin, and after the administration of 500 mg the ventricular tachycardia reverted to normal sinus rhythm. Diphenylhydantoin was administered orally (100 mg four times a day), but was discontinued after eight days, following development of external ophthalmoplegia. Oral administration of procainamide hydrochloride, 500 mg every six hours, was started. The external ophthalmoplegia resolved six days after cessation of diphenylhydantoin. The myocardial infarction proceeded uneventfully until the 22nd day of hospitalization, 14 days after starting procainamide hydrochloride.

The patient then had a fever of 103°F, accompanied by shaking chills and malaise. The white blood cell count at this time was 6,900/cu mm with 62 segmented neutrophils, 17 band forms, eight lymphocytes, one monocyte and two eosinophils. The sputum culture revealed normal flora, and the blood and urine cultures were sterile. Although there was no clinical evidence of infection, cephalothin and colistin administration was begun.

On the next day the temperature rose to 105.5°F and a generalized maculopapular eruption appeared. The antibiotics were discontinued and lincomycin and kanamycin administration started. Remittent fever, with daily elevation to 104°F, continued for the next two days, accompanied by shaking chills and generalized malaise. The top of the spleen was palpated. The white blood count ranged from 7,000 to 9,000 at this time. On the fifth day of daily remittent temperature elevation, it was finally suspected that the fever, chills, and eruption might be due to procainamide hydrochloride and all medications were discontinued. Within 24 hours the temperature had dropped to 103°F and subsequently the patient continued to have a low-grade fever (100°F to 101°F) for six days after procainamide hydrochloride had been discontinued. This was attributed to the presence of an exfoliative dermatitis and furuncu-

patient 3	0.75	14	10.5	50
Present patient	2	14	28	36

losis which developed in the sites of the original cutaneous eruption. Eighteen days after the original febrile episode the patient was challenged with a single dose of 250 mg of procainamide hydrochloride. Within six hours his temperature rose to 104°F, and he had shaking chills and malaise but was afebrile within 36 hours. No skin rash occurred on this occasion. The white blood cell count was 7,000/cu mm. Blood and urine cultures were negative, and sputum culture revealed normal flora. Examination of the serum for lupus erythematosus factor and antinuclear globulin were negative. He continued to have an uneventful convalescence and was discharged on the 54th hospital day.

Comments

Patients who have developed fever due to procainamide administration have been in two general groups: those who develop fever, usually with chills and sometimes with dermatitis, after one to fifteen days of drug administration, and those who develop a lupus-like syndrome, usually with fever, after three weeks to twenty-two months of drug administration.

In eight reported patients¹⁻⁶ fever began within 15 days after oral administration of less than 24 grams of the drug (Table 1A). The temperature elevations ranged between 101° and 106.2°F with daily elevations of a remittent nature as long as the drug was continued. The cause of the fever was not immediately recognized; however, the fever disappeared within 50 hours after discontinuation of the drug.

When procainamide was re-administered to a patient who had previously had fever due to this drug, fever appeared in less than 24 hours and lasted no more than 24 hours¹⁻⁶ (Table 1B). The maximum elevation of temperature was similar to that which occurred during the initial drug

administration. In the patient described in this report, readministration of 0.25 grams of procainamide orally was followed within six hours by the reappearance of fever which lasted approximately 16 hours.

patient 3	0.25	7	105.2	8
Present case	0.25	< 6	104.0	< 16

Shaking chills, malaise, dermatitis, anorexia, nausea, arthralgia, headache, nasal congestion, diaphoresis, diuresis, vomiting and paresthesia have been observed. Splenomegaly, adenopathy, and peripheral vasoconstriction have been found on physical examination (Table 1C). The relation of the dermatitis to procainamide administration is not certain since the patient was also receiving Cephalothin and Colistin. When our patient was later challenged with a single dose of procainamide, fever, shaking chills and malaise recurred, but the dermatitis did not reappear.

Except for the appearance of eosinophilia and cold agglutinins in one patient each, no significant laboratory findings have been noted during or after the development of drug fever (Table 1D).

Likewise there have been no reports of lupus erythematosus or of anti-nuclear antibody in the reported instances of procainamide administration in which fever developed or in the patient who was studied in this report.

Patients who have developed evidence of hypersensitivity to procainamide after longer periods of drug administration have usually had one or more manifestations of a lupus-like syndrome; the commonest sign or symptom has been arthritis. Other signs and symptoms have included pleurisy, fever, pneumonitis, weakness, hepatomegaly, myalgia, skin lesions, pericarditis, splenomegaly, lymphadenopathy, central nervous system manifestations, gangrenous digits and ulcerated tonsils (Table

patient 3	5,100	0	Coombs' negative.
Present case	6,900	1	LE preparation negative. Antinuclear antibodies negative.

2A). Laboratory findings include antinuclear antibodies, the lupus erythematosus factor, anemia, a positive latex fixation test, leukopenia eosinophils, hypergammaglobulinemia, thrombocytopenia. Coomb's positive test, and proteinuria (Table 2B). The signs and symptoms of the lupus-like syndrome have subsided after discontinuation of procainamide, but serologic changes have persisted for longer periods, even as long as two years.¹⁰ The administration of adrenal cortical steroid has been reported to produce prompt defervescence and subsidence of symptoms, with or without^{10,12,13,15,16} continued administration of procainamide.

The nine patients (eight reported and one described) who developed fever after one to 15 days of procainamide administration had none of the serologic manifestations of the lupus-like syndrome, while the 36 who developed the syndrome

after three weeks to 22 months had one or more serologic manifestations of the syndrome. The duration of drug administration appears to be important in the development of the syndrome. The development of fever after one to 15 days of procainamide administration may be due to a hypersensitivity reaction that represents an early stage of the lupus-like syndrome. The rate at which other manifestations of the syndrome develop with continued administration of the drug will probably be found to vary with constitutional factors, including immunologic responsiveness.²¹ The importance of recognition of the febrile and lupus-like reactions to procainamide, and of prompt discontinuation of the drug, is obvious.

The patient who was described developed an unusual reaction to diphenylhydantoin, manifested by external ophthalmoplegia, a reaction not mentioned in several reviews of the effects of this drug.²²⁻²⁴ Although the patient was not challenged with diphenylhydantoin, it seems likely that the drug was responsible for the changes in extraocular movement that were observed.

Generic and Trade Names of Drugs

Procainamide hydrochloride (Pronestyl)
Sodium cephalothin (Keflin)
Colistin sulfate (Coly-Mycin)
Kanamycin sulfate (Kantrex)
Lincomycin hydrochloride monohydrate (Lincocin)
Diphenylhydantoin (Dilantin)

Humanism at the Bedside

ARNOLD LIEBERMAN, M.D.*

BEING PARTIAL TO ourselves, we humans use this word as the antonym of Animal. Humanism evokes such synonyms as, sympathetic, clement, compassionate, touched to the heart—the list is long. These desirable terms are in contrast to mechanistic, unthinking, callously oppressive—words lumped together as animalistic or *inhuman*: in short, brutish. Why is a discussion of “Humanism at the Bedside” acquiring increasing relevance to the physician of today?? Is it, perhaps, because the public image of the doctor continues to shrink? In inverse proportion to his enormously expanding knowledge and skill, people at large hold him in ever shriveling esteem. No longer a beloved member of the families seeking his ministrations, we appear to be sinking to a level with such hired hands as truck drivers, plumbers and what have you.

In 1891, Sir Luke Fildes depicted a most memorable tableau. In the predawn darkness, a child is lying on two chairs pulled together; the parents are hovering in the back-ground. In the very center of the picture, the family physician is sitting, chin propped by the hand even as his elbow rests on his knee. The little black bag is lying on the floor: *so* pathetically useless: The crisis—the issue of life and death—is up to God; But the doctor—the intensely involved member of the family—is at one with the parents awaiting the answer from on High.

In 1938, Dr. A. Hertzler wrote the best seller, “Horse and Buggy Doctor”. This volume caressingly conjures the Kansas pioneer making his rounds at the turn of the century. What did he carry in his buggy besides digitalis, ether—some dressings, splints and antiseptics: maybe, even a Simpson forceps. Ah, yes: In abundant measure he had intense identification with all sod-busters of his horizon scanning lonely prairies: He was totally devoted to the solitary farmers. Despite distance, fatigue, road hazards—when called, he came forthwith: Within the limits of his compassion and ability, he gave his all. Remuneration? Those farmers gave what they could . . .

In the second decade of just this century, the

famous Flexner reports spelled out the short comings of American Medicine. The *what* and the *how* of the reforms needed to put the U.S.A. into the 20th century were spelled out. The doctors of today are the beneficiaries of the better teaching (and the knowledge explosion) that followed the end of WWI and is still accelerating at a logarithmic pace. 90% of today's most useful drugs and techniques were unknown as late as 1950: So many previously doomed millions are being saved that we are experiencing a veritable Population Explosion with all its attending problems: but that is another issue.

With expanding professional knowledge and expertise, there arises increasing specialization in ever narrowing sub-specialties. Now we see our problem; who is rendering the *primary* care?? With whom does the patient and his family identify in the first place? Let us affirm that the graduates of today are as dedicated to their profession as were their elders of yesteryear. But: how can the orthopod of today, restricting himself to surgery of the hand alone and getting all his surgery only by referral, become the family physician? The very eminent cardiac surgeon performing coronary cineradiography only—can the patient regard him as anything more than a very skillful technician?

It is obvious that multi-staffed, superbly equipped clinics and multi-purposed ambulatories and home care units are the wave of imminent tomorrow. But: after all is said and done, we are still faced with the ineluctable fact that 2/3 of all patients require only sympathy and understanding. Which doctor will become the Father Confessor of yesteryear? Modern hospitals are acquiring Intensive Care Units with all the paralleling complexes. Computers can feed “bits” of knowledge to the M.D. or R.N. sitting at the nurses' station—or in a center a continent away. Regular para-medical technicians can service the patient and alter therapy at phoned or wired command; we are enthralled by “hardware” and “software”. The computer commanders are adding a new termin to their jargon; are you familiar with ‘liveware’? Human intelligence, no

*New York, N.Y.

less . . .

It is clear that we see an increasing priesthood serving the Moloch of the machine. We have a growing hierarchy of prestige seeking bureaucrats. But: who will be rendering the primary care? Who will amalgamate with the patient and his

family? This Holy Grail will be found: hopefully sooner than later. We just must have absolute Faith that the answers will be forthcoming within the coming decade: Let our best minds dedicate themselves to this inspiring goal. A general consensus will allow its implementation within the decade.

Historic Hospital The Pennsylvania Hospital, Philadelphia

The Pennsylvania Hospital as it appeared in 1814. Courtesy National Library of Medicine, Bethesda, Maryland.

The oldest hospital in the United States is the Pennsylvania Hospital at Philadelphia. The East Wing, shown on the right in the engraving, was completed in 1756; the inscription for its cornerstone was composed by Benjamin Franklin, who was president of the hospital's Board of Managers from 1755 to 1757.

In the 1750's Philadelphia was a commercial seaport and agricultural market of some 15,000 inhabitants. Townspeople complained that the hospital was being built too far from what was then the center of town; although the complaint seems groundless now. There being no professional architect in the colonies, the design and construction of the hospital were entrusted to one of the members of the Board of Managers, Mr. Samuel Rhoads, a Philadelphia builder. The soundness of his work is attested by the fact that the building is still in use as a hospital.

By 1763 the hospital census was constantly upwards of one hundred patients. Male patients were assigned to the first floor, females to the second, and mental patients were confined in locked facilities in the basement. In the early years curious townsfolk would gather about the ground floor windows observing or even teasing the "lunaticks." A fence was built around the windows, and, until more humane measures were adopted in 1791, the curious were charged an admission fee to watch the antics of the insane.

The West Wing was completed in 1796 and the Central Building in 1804. The third floor of the Central Building was covered by a skylight and equipped with concentric rows of elevated benches to serve as a clinical and surgical amphitheater. This feature was much admired by Charles Bullfinch, the architect of the Massachusetts General Hospital, who incorporated into his design a similar structure which became famous as the "Ether Dome."

Who knows what evil lurks in the mucous membranes?

Ornade[®] knows.

Each Spansule[®] (brand of sustained release capsule) contains 8 mg. of Teldrin[®] (brand of chlorpheniramine maleate); 50 mg. of phenylpropanolamine hydrochloride; and 2.5 mg. of isopropamide, as the iodide.

Knows the public's enemies — nasal congestion, runny nose, sneezing, watery eyes.

Knows what to do about them too.

All through the dark night of upper respiratory difficulty, while ordinary cold remedies wear off, the decongestant, antihistamine, and drying agent in 'Ornade' fight the never-ending battle for comfort, symptomatic relief, and free airways.

Ornade[®]. Why not let it help fight your patient's cold war.

Before prescribing, see complete prescribing information in SK&F literature or *PDR*.

Indications: Upper respiratory congestion and hypersecretion associated with: the common cold; acute and chronic sinusitis; vasomotor rhinitis; allergic rhinitis (hay fever, "rose fever," etc.).

Contraindications: Hypersensitivity to any component; concurrent MAO inhibitor therapy; severe hypertension; bronchial asthma; coronary artery disease; stenosing peptic ulcer; pyloroduodenal or bladder neck obstruction. Children under 6.

Warnings: Caution patients about activities requiring alertness (e.g., operating vehicles or machinery). Warn patients of possible additive effects with alcohol and other CNS depressants.

Usage in Pregnancy: In pregnancy, nursing mothers and women who might bear children, weigh potential benefits against hazards. Inhibition of lactation may occur.

Effect on PBI Determination and ¹³¹I Uptake: Isopropamide iodide may alter PBI test results and will suppress ¹³¹I uptake. Substitute thyroid tests unaffected by exogenous iodides.

Precautions: Use cautiously in persons with cardiovascular disease, glaucoma, prostatic hypertrophy, hyperthyroidism.

Adverse Reactions: Drowsiness, excessive dryness of nose, throat or mouth; nervousness; or insomnia. Also, nausea, vomiting, epigastric distress, diarrhea, rash, dizziness, weakness, chest tightness, angina pain, abdominal pain, irritability, palpitation, headache, incoordination, tremor, dysuria, difficulty in urination, thrombocytopenia, leukopenia, convulsions, hypertension, hypotension, anorexia, constipation, visual disturbances, iodine toxicity (acne, parotitis).

Supplied: Bottles of 50 capsules.

Known special hormonal needs

"The pill" to your patient

Demulen,
a 50-mcg.
low-estrogen" pill,
is a logical
first choice.

3. If your patient requires
a different hormonal balance—
temporarily or for the
long term—
Searle offers you alternatives.

For a "standard"
50-mcg. start

Demulen®

Available in 21- and 28-pill schedules.
Each white tablet contains: ethynodiol
diacetate 1 mg./ethinyl estradiol 50 mcg.
Each pink tablet in Demulen-28® is a
placebo, containing no active ingredients.

A moderately
estrogen-dominant
combination with low
androgenic activity.*

Product of Searle & Co.
San Juan, Puerto Rico 00936

When slightly more
estrogenic activity is
indicated

Ovulen®

Available in 20-, 21- and 28-pill schedules.
Each white tablet contains: ethynodiol
diacetate 1 mg./mestranol 0.1 mg.
Each pink tablet in Ovulen-28® is a placebo
containing no active ingredients.

A centrally balanced
estrogen/progestogen
combination.*

Product of Searle & Co.
San Juan, Puerto Rico 00936

For the woman who
clearly needs more
estrogen or is sensitive
to other progestogens

Enovid-E®

Available in 20- and 21-pill schedules.
Each tablet contains: norethynodrel 2.5
mg./mestranol 0.1 mg.

An estrogen-dominant
combination with no
androgenic activity.*

Product of Searle Laboratories

Where "The Pill" Began

Note: Oral contraceptives are complex medications. As with all medications they should
be prescribed with discriminating care, and only after reference to full prescribing information.
For brief summary of prescribing information, please see next page.

If one "pill" were right for every woman, we'd make it.

Ovulen® Available in 20-, 21- and 28-pill schedules

Each white tablet contains: ethynodiol diacetate 1 mg./mestranol 0.1 mg.
Each pink tablet in Ovulen-28® is a placebo, containing no active ingredients.

Demulen® Available in 21- and 28-pill schedules

Each white tablet contains: ethynodiol diacetate 1 mg./ethinyl estradiol 50 mcg.

Each pink tablet in Demulen-28® is a placebo, containing no active ingredients.

Actions—Ovulen and Demulen act to prevent ovulation by inhibiting the output of gonadotropins from the pituitary gland. Ovulen and Demulen depress the output of both the follicle-stimulating hormone (FSH) and the luteinizing hormone (LH).

Special note—Oral contraceptives have been marketed in the United States since 1960. Reported pregnancy rates vary from product to product. The effectiveness of the sequential products appears to be somewhat lower than that of the combination products. Both types provide almost completely effective contraception.

An increased risk of thromboembolic disease associated with the use of hormonal contraceptives has now been shown in studies conducted in both Great Britain and the United States. Other risks, such as those of elevated blood pressure, liver disease and reduced tolerance to carbohydrates, have not been quantitated with precision.

Long-term administration of both natural and synthetic estrogens in subprimate animal species in multiples of the human dose increases the frequency of some animal carcinomas. These data cannot be transposed directly to man. The possible carcinogenicity due to the estrogens can be neither affirmed nor refuted at this time. Close clinical surveillance of all women taking oral contraceptives must be continued.

Indication—Ovulen and Demulen are indicated for oral contraception.

Contraindications—Patients with thrombophlebitis, thromboembolic disorders, cerebral apoplexy or a past history of these conditions, markedly impaired liver function, known or suspected carcinoma of the breast, known or suspected estrogen-dependent neoplasia and undiagnosed abnormal genital bleeding.

Warnings—The physician should be alert to the earliest manifestations of thrombotic disorders (thrombophlebitis, cerebrovascular disorders, pulmonary embolism and retinal thrombosis). Should any of these occur or be suspected the drug should be discontinued immediately.

Retrospective studies of morbidity and mortality conducted in Great Britain and studies of morbidity in the United States have shown a statistically significant association between thrombophlebitis, pulmonary embolism, and cerebral thrombosis and embolism and the use of oral contraceptives. There have been three principal studies in Britain¹⁻³ leading to this conclusion, and one in the United States. The estimate of the relative risk of thromboembolism in the study by Vessey and Doll³ was about sevenfold, while Sartwell and associates⁴ in the United States found a relative risk of 4.4, meaning that the users are several times as likely to undergo thromboembolic disease without evident cause as non-users. The American study also indicated that the risk did not persist after discontinuation of administration and that it was not enhanced by long-continued administration. The American study was not designed to evaluate a difference between products. However, the study suggested that there might be an increased risk of thromboembolic disease in users of sequential products. This risk cannot be quantitated, and further studies to confirm this finding are desirable.

Discontinue medication pending examination if there is sudden partial or complete loss of vision, or if there is a sudden onset of proptosis, diplopia or migraine. If examination reveals papilledema or retinal vascular lesions medication should be withdrawn.

Since the safety of Ovulen and Demulen in pregnancy has not been demonstrated, it is recommended that for any patient who has missed two consecutive periods pregnancy should be ruled out before continuing the contraceptive regimen. If the patient has not adhered to the prescribed schedule the possibility of pregnancy should be considered at the time of the first missed period.

A small fraction of the hormonal agents in oral contraceptives has been identified in the milk of mothers receiving these drugs. The long-range effect to the nursing infant cannot be determined at this time.

Precautions—The pretreatment and periodic physical examinations should include special reference to the breasts and pelvic organs, including a Papanicolaou smear since estrogens have been known to produce tumors, some of them malignant, in five species of subprimate animals. Endocrine and possibly liver function tests may be affected by treatment with Ovulen or Demulen. Therefore, if such tests are abnormal in a patient taking Ovulen or Demulen, it is recommended that they be repeated after the drug has been withdrawn for two months. Under the influence of progestogen-estrogen preparations preexisting uterine fibromyomas may increase in size. Because these agents may cause some degree of

fluid retention, conditions which might be influenced by this, such as epilepsy, migraine, asthma, cardiac or renal dysfunction, require careful observation. In breakthrough bleeding, and in cases of irregular bleeding per vaginam, nonfunctional causes should be borne in mind. In undiagnosed bleeding per vaginam adequate diagnostic measures are indicated. Patients with a history of psychic depression should be carefully observed and drug discontinued if the depression recurs to a serious degree. The possible influence of prolonged Ovulen or Demulen therapy on the pituitary, ovarian, adrenal, hepatic or uterine function awaits further study. A decrease in glucose tolerance has been observed in a significant percentage of patients on oral contraceptives. The mechanism of this decrease is obscure. For this reason, diabetic patients should be carefully observed while receiving Ovulen or Demulen therapy. The age of the patient constitutes no absolute limitation, although treatment with Ovulen or Demulen may mask the onset of the climacteric. The pathologist should be advised of Ovulen or Demulen therapy when relevant specimens are submitted. Susceptible women may experience an increase in blood sugar following administration of contraceptive steroids.

Adverse reactions observed in patients receiving oral contraceptives—A statistically significant association has been demonstrated between use of oral contraceptives and the following serious adverse reactions: thrombophlebitis, pulmonary embolism and cerebral thrombosis.

Although available evidence is suggestive of an association of a relationship has been neither confirmed nor refuted for the following serious adverse reactions: neuro-ocular lesions, e.g., retinal thrombosis and optic neuritis.

The following adverse reactions are known to occur in patients receiving oral contraceptives: nausea, vomiting, gastrointestinal symptoms (such as abdominal cramps and bloating), breakthrough bleeding, spotting, change in menstrual flow, amenorrhea or bleeding after treatment, edema, chloasma or melasma, breast changes (tenderness, enlargement and secretion), change in weight (increase or decrease), changes in cervical erosion and cervical mucus, suppression of lactation when given immediately postpartum, cholestatic jaundice, migraine, rash (allergic), rise in blood pressure in susceptible individuals and mental depression.

Although the following adverse reactions have been reported in users of oral contraceptives, an association has been neither confirmed nor refuted: anovulation post treatment, premenstrual syndrome, changes in libido, changes in appetite, cystitis-like syndrome, headache, nervousness, dizziness, fatigue, backache, pruritus, loss of scalp hair, erythema multiforme, erythema nodosum, hemorrhagic eruption and itching.

The following laboratory results may be altered by the use of oral contraceptives: hepatic function: increased sulfobromophthalate retention and other tests; coagulation tests: increase in prothrombin Factors VII, VIII, IX and X; thyroid function: increase in plasma butanol extractable protein bound iodine, and decrease in iodine take values; metyrapone test and pregnanediol determination.

Where "The Pill" Began

be and the more frustrating it will prove to the individual student or physician. Optimal resolution, then, might well be sought at the doors of admission to the medical school.

Would it be unreasonable to expect the student at the time he seeks admission to medical school to select a specific professional career within the field of medicine? Should he be required to declare whether he intends to become a surgeon, a psychiatrist, or otherwise? At comparable age and academic status, candidates for the Ph.D. degree must make a similarly specific choice. Admission to university graduate schools commonly is by way of a specific department and discipline. Is a career in chemistry remarkably more distinct from a career in English language and literature than is a career in surgery from a career in psychiatry? Admittedly, though, the usual recipient of a bachelor's degree believes he has basis in his collegiate studies to judge whether his talents and competences fit him for graduate courses in chemistry, on the one hand, or, on the other, for similarly advanced courses in a field as remote from chemistry as is English. He may rightly judge his college courses provided scant basis for a career choice between surgery and psychiatry. This deficiency could be removed, though, by appropriately designed experiences at the pre-baccalaureate degree level.

Suppose this deficit in the student's knowledge of medical careers could be remedied and he might reasonably be asked to seek admission to a specific department in the medical school. Such an admissions policy would offer certain advantages, among which are the following:

1. An opportunity would be provided to departmental leadership in specialties notably in short supply of professional personnel to recruit from the total pool of individuals who wish to become physicians. Some 50% of qualified individuals in this pool will, under existing circumstances, not be admitted to medical school.

2. Professional responsibilities and skills differ widely from one medical or surgical specialty to another. Certain individuals highly qualified for one specialty but not as well rounded as the usually successful candidate may be found among the 50% or more of candidates currently rejected by the medical schools. Faculty members in a given discipline should be uniquely capable of recognizing individuals highly talented for discharge of responsibilities of their specialty. Humanistic

qualities and talents in the student might thereby achieve influence competitive with that possessed currently by results of examinations that reflect more readily quantifiable components of intelligence and human behavior.

3. A departmental head might identify within the ranks of his allied health training programs an occasional student of exceptional talent, motivation, and accomplishments; such an individual could be assured medical school admission to the chairman's department on completion of studies crucial to his "premedical" education.

4. Members of the faculty of a given department would have opportunity to guide the educational experiences of a small group of students to whom they could relate intimately throughout undergraduate and graduate medical educational years. In such context, the medical student would be assured exposure to the highly personalized faculty-resident relationship that prevails in residency programs generally in the United States.

5. Financial support of the program might be attracted from sources desirous of encouraging recruitment to specialties currently deficient in manpower.

However, a number of major adaptive responses would be needed, both at the premedical and medical school level, before such a program of departmental admissions could become operable. In Mayo Medical School, we are probably five to 10 years removed from overt experimentation with such an undertaking, though we are including elements of the concept in our present admissions procedures.

Meanwhile, the move toward earlier differentiation of medical students into disciplinary career interests is occurring in the form of medical school "tracks," that is, clinical or laboratory "majors." The Figure displays the tracks that have been proposed for Mayo Medical School. Within the first two years of our curriculum, we have attempted to compress an overview of medical science and medical practice comparable to that achieved in the full four years of medical school by the students of earlier decades. By the time the students complete the second year clerkship, we anticipate many of them will have gained insights sufficient to permit them, in counsel with faculty, to design an integrated pre- and post-M.D. training program in a medical, surgical, or laboratory discipline.

Incorporated in the final two pre-M.D. years

will be a six to 15 month experience in a laboratory of clinical or basic science, or in some other form of scholarly endeavor particularly appropriate to the students' career goals. Such an experience was once component to the residency training in Mayo Graduate School. The increasing demands of specialty board examinations and the high cost of supporting residents' stipends have led to a near elimination of this experience from many of our post-M.D. specialty training programs. We believe this loss should not go unremedied and we think incorporation of a comparable experience in the pre-M.D. component of the integrated undergraduate and graduate medical educational program will effect such restitution.

If the student and his faculty adviser discover in due course that they have erred in selection of the student's career, then transfer to a more appropriate program will be accomplished. If this transfer occurs in the pre-M.D. period, then probably little will be lost in comparison with what would have been gained under more traditional curricular processes. If the student and his counselor have made a correct choice, then the student will have the advantage of early concentration of his talents and energies on goals especially appropriate to his own career.

The processes just described may indeed increase the efficiency and relevance of the formal years of medical education. If, though, the student has been admitted to medical school without commitment to a specialty and if he is given free choice among the several medical, surgical, and laboratory disciplines throughout the four years of medical school, then what reason have we to expect that the optimal number of students will end up pursuing careers in primary medical care, "Generalists," as the label reads at the bottom of the diagram in the Figure, and the proper number in more narrowly delimited disciplines labeled "Specialists"? Such optimal distribution has not been produced by permitting free choice to students of the past several decades.

In recent years, to be sure, certain faults in the academic process that contributed to the medical students' near universal selection of a specialty career have been partially remedied. These students increasingly are exposed to the role of the primary physician; family practice has been accorded status as a specialty and its representatives brought on to the medical school faculty; efforts are being made to improve the quality of

professional life of the primary physician. All this is helpful and desirable. I can but wonder if it is enough.

If we believe that resolution of faulty distribution of physicians among the several specialties will require measures of greater and more immediate consequence than those currently applied, we might well consider their initiation at the juncture between the pre- and post-M.D. training of the physicians. But a change in the market place for residency training must be effected if maldistribution of physicians among the specialties is to be corrected by intervention at this juncture between pre- and post-M.D. training. The number of openings in residency programs in the United States today is sufficiency great in relation to the number of graduates from United States medical schools that each graduate almost certainly can secure an appointment in whatever specialty discipline he elects. Hence, if the correct numbers of specialists in several disciplines are to be derived through the process of post-M.D. training, it will be necessary to define precisely how many residency positions in each discipline are available in the United States. This could be effected by collaboration between the residency accrediting agencies and the sources of funding for those residencies.

Such collaboration is indeed in process and is manifested in the preferential funding of family practice residencies by federal and state authorities. Only one step separates preferential funding of certain programs from limitation in funding of others. Quotas of residency positions by specialty on a national basis may be a development but a few years removed. As a consequence of such regimentation of opportunities for specialty training, certain physicians with a newly acquired M.D. will confront a limitation on their career choices. However, in a well-run system such as the intern matching plan, such limitation would be the product of the physician's failure in a fair and open competition for one of limited numbers of residency slots in certain specialties. He would still have open to him a medical career in one or several other disciplines, all of them providing a worthy challenge to his talents and rich opportunity for a life of well-rewarded service. The winds of chance may in fact blow him into a career for which he is better suited than the one to which his own judgment would have consigned him! If this process is deemed coercive, I can

only surmise it is likely to be less so than the alternative processes devised by a society frustrated by our profession's inadequate efforts to resolve the problem of maldistribution of physicians by specialty.

The Figure addresses major problems in physician manpower production. Our comments on the chart have revealed that any change in what has been the traditional process of career choice and specialty training among medical students and residents will entail a set of new compromises, some of them painful. Almost certainly, the stu-

dent will be encouraged to make a decision on his choice of career earlier in the course of his medical education and he may be forced to accept direction with respect to that choice by forces he would prefer to avoid. We shall do well, though, as responsible members of the profession, to study the factors involved in career choices and seek thereafter so to mold the admissions' processes and the student's choice of a career that the best interests of all concerned will be well served.

Raymond D. Pruitt, M.D.
Mayo Clinic and Mayo Foundation
Rochester, Minnesota

Meconium Aspiration in the Newborn

THE PROBLEM of meconium aspiration is put into perspective by Strickland and Edwards in their article.* Although there are a group of patients that do well with little or no treatment, the patient with respiratory distress associated with meconium aspiration can be one of the most difficult problems in pulmonary medicine. Unlike the infant with other types of respiratory distress which generally has an acute onset and then stabilizes, the child with meconium aspiration can become steadily and relentlessly worse over a period of days. They are very likely to develop a pneumothorax secondary to the ball valve effect of the meconium in the bronchioles.

The thesis that the problem in meconium aspiration is to a large extent secondary to the inspissated material in the trachea and main stem bronchi, is attractive. Dr. Strickland's observation

of the high number of infants with meconium in the trachea would tend to support this. This concept would make it imperative that as much of the material as possible be removed.

The problem which does not seem to be well dealt with in the article is that of the hypoxia which was the initiating cause of the passage of meconium into the amniotic fluid. Should a person delay vital oxygen therapy long enough to do a tracheal lavage? In the previous study, Dr. Strickland demonstrated that lavage lowers the P_{aO_2} .¹

I feel that adequate suctioning is indicated. I do not know whether the efficacy of lavage with concomitant delay in oxygen therapy and its tendency to lower P_{aO_2} has been well proven.

David B. Klain, M.D.
Children's Health Center
Minneapolis, Minnesota

Snowmobiling Associated with Maxillofacial Injuries

SNOWMOBILES AND motorcycles connote fun, excitement, and sometimes a means of transportation. It also means with alarming frequency the reality of sprains, lacerations, fractures, concussions, and even death. I shudder to think that one out of every 25 Minnesotan snowmobilers may get injuries, varying from a sprain to a fatality.* There was an increase of two and a half times in mortality (33 persons) in the last fifteen months of the study compared to 13 deaths during the same period, in 1969 to 1970. The injuries involve the maxillofacial areas in 26% and the upper and lower extremities in 61%, resulting in prolonged morbidity and serious residual disability. Dr. Karleen strongly points out the way to minimize the problem through prevention, better rules and regulations, and strict

adherence to them. Just as important is the recognition by the manufacturers of the problems so the vehicle can be made with better safety devices. However safe the vehicle is, the ultimate responsibility still remains with the driver. As physicians, we have to face the facts that snowmobiles and motorcycles are here to stay and therefore injuries are going to occur. The Emergency Room facilities and medical personnel in the rural towns should be upgraded to handle such emergencies, and better transportation must be available to transfer these patients to larger centers. Many times the victim has multiple injuries and would therefore require a sophisticated Emergency Room facility as well as multiple specialty medical services.

Ramon B. Gustilo, M.D.
Head, Department of Orthopaedics
Hennepin County General Hospital

Alcohol and Chemical Dependency

ALCOHOL AND RELATED chemical dependencies are among the most under diagnosed illnesses of our time. There are an estimated six to nine million alcoholics in the United States, and about 80% of general hospital admissions are associated with the disease of alcoholism. Yet formal courses in this subject are offered in only a very few medical schools. Therefore, recent efforts of the University to initiate study in this area are to be encouraged.

It may be a long wait before the arrival of promised federal funds; hopefully, our state legislature and the medical school will recognize

the extreme need for our physicians to acquire much needed knowledge in this field and take action immediately. We have begun, but much more is required; a few lectures and seminars are not adequate preparation for our physicians. While physicians cannot be considered the ultimate treatment resource for everyone who suffers from alcohol or chemical dependency, we must be able to diagnose these conditions if satisfactory referrals are to be made.

St. Paul, Minnesota

Ophthalmia Neonatorum

AS A RESULT of changing morals, a dramatic rise in the incidence of venereal disease has occurred. Boone et al.* have, therefore, chosen a timely subject for inclusion in a general medical journal such as MINNESOTA MEDICINE. Although gonorrheal ophthalmia is still an infrequent disease, it is

probably on the increase and since prompt treatment is necessary to prevent possible visual damage which may occur, a high index of suspicion of any purulent conjunctivitis in the newborn or adults must be present. In prying open lids which are swollen shut, the doctor must be careful that pus under pressure does not squirt him in the eye! Although by no means diagnostic, as other

*Boone WB et al.: Ophthalmia neonatorum. The value of prophylactic treatment. Minnesota Med 56:940, 1973.

1974

eye infections of the newborn may also give a purulent discharge, a thick creamy pus is characteristic of gonorrheal ophthalmia. Pronounced conjunctival and lid edema usually are also present.

The authors have concisely covered all aspects of the prophylactic controversy. It has been present a long time and undoubtedly will be with us in the future. Because of the danger of resistance to antibiotics developing, I agree with the authors that 1% Silver Nitrate is probably

the prophylaxis of choice. Prophylaxis with either 1% Silver Nitrate or Penicillin has been shown to reduce the incidence of gonorrheal ophthalmia and thus to abandon all prophylaxis as some have advocated would seem particularly unwise in the presence of an increasing incidence of gonorrhea. We must not feel that prophylaxis in the newborn is 100% effective in preventing the disease for no single dose of any kind will prevent all the cases.

Minneapolis, Minnesota

Letters to the Editor

Dear Editor:

Physicians are often asked to give statements with respect to a patient's ability to work. These statements are required of patients who apply for Aid to Disabled, Social Security disability, aid from Department of Veteran's Affairs, Workman's Compensation, and General Assistance.

Many times the physician is unrealistic when making his evaluation and appears unaware of job requirements in today's market. Recently a fifty-nine year old woman with a second grade education was told that she could work at a job where she "sat down." She is suffering from severe arthritis and hypertension and has done only hard physical work since early childhood. There is no sedentary occupation for which she qualifies, nor can she pass a physical examination. Her doctor's statement is now preventing eligibility for the new Federal Supplementary Security Income Program which starts January 1, 1974.

Let us ask the medical profession to use judgment and common sense in carrying out its responsibility in this area.

Leonore Y. Kaplan
Social Worker
Department of Public Relief
Minneapolis, Minnesota

Dear Editor:

A series of five one-a-month television programs is to be presented on Public Broadcasting stations across the country every Fourth Monday evening. Subjects of the series are: *Heart Disease* (November 19); *Inborn Genetic Defects* (December 17); *Pulmonary Disease* (January 14); *Trauma* (February 11); and *Cancer* (March 11).

We would like your help in telling your readers about the series, and in encouraging them to work with their local PBS stations and health organizations on community out-reach programs.

H. J. Barnum, M.D.
New York, New York

Editor's Note: In Minnesota the following stations will broadcast the programs: KWCM-Ch 10 Appleton, KAVT-Ch 15 Austin, WDSE-Ch 8 Duluth, KTCA-Ch 2 St. Paul/Minneapolis.

Letter to the Editor

Dear Editor:

The editorial by Brown,* raises questions regarding our study of gastric malignancy.[†] The first relates to the accuracy of gastroscopic biopsy in gastric carcinoma. Dr. Brown stated that only one of 15 patients from the group with negative upper gastrointestinal series and positive endoscopies had a positive biopsy. This statement is at variance with the data presented. In this group of 14 (not 15) patients, there were 13 biopsies of which 9 were positive for carcinoma. This is so stated in the article. The point of confusion may relate to the fact that there was one patient thought to have a benign gastric ulcer at endoscopic examination whose upper gastrointestinal series was normal. The biopsy in this patient was positive and is included in the 9 of 13 positive biopsies. It was further pointed out in the review that 35 out of a total of 42 biopsies were positive for carcinoma.

The question is appropriately raised as to how many patients in group I (both roentgenographically and endoscopically positive for carcinoma) needed the endoscopy in view of the radiographic interpretation. The criteria of a positive roentgenographic diagnosis of cancer used in this review allowed even a passing mention of malignancy to be a *positive* diagnosis for statistical analysis of the material. Thus, in many of these instances the endoscopy added considerable support to an otherwise uncertain clinical situation.

The third question and perhaps the most important one asks, "Do the results of the examination in any real way alter the patient's diagnosis or management?" In view of the fact that there was a 63% accuracy of x-ray diagnosis of gastric malignancy it is clear that significant alteration in patients' diagnoses did result from the endoscopic evaluation. Management appeared to be clearly altered also by performance of the endoscopic examination as 87.5% underwent an attempt at curative resection if the gastric malignancy was only evident on endoscopic examination. This stands in contrast to the 29% if both radiologic and endoscopic criteria for malignancy were met.

There is no question that a prospective study would add further information and validity to an analysis of the usefulness of upper gastrointestinal endoscopy. Nevertheless it appears very clear from this report and others cited, that one should not apologize for the performance of upper gastrointestinal endoscopy in view of its proven value.

We believe that hospital days saved prior to definitive diagnosis and therapy justifies the greater expense of endoscopy as opposed to roentgenographic evaluation of the stomach in these patients. Perhaps we should develop a means of performing the examinations with sufficient frequency, facility and availability that the cost could be appropriately reduced if this is shown to be a deterrent. Clearly it should not be one and discussions of its accuracy should not be confused with discussions of its cost effectiveness.

Case Report

Multiple Hemangioblastomas of Central Nervous System

LASHMAN W. SORIYA, M.D.,* DANIEL E. NIJENSOHN, M.D.* and
ROSS H. MILLER, M.D.*

IN 1926, LINDAU¹ OBSERVED the presence of hemangiomas of the retina (retinal angiomas) frequently associated with small angiomas of the central nervous system. This disease was then named "angiomas of the central nervous system" and the combination of retinal angiomas with the cerebellar hemangioblastoma came to be known as "Hippel-Lindau syndrome."

Lindau had stated that in 25% of patients with angiomas of the retina, cerebellar or medullary hemangioblastoma or both developed. In an extensive series of cerebellar hemangioblastomas, however, Dandy² found only two instances of associated retinal tumor.

Location

In the central nervous system, hemangioblastomas usually are restricted to the metencephalon and the spinal cord. Only in isolated cases has the site been above the tentorium cerebelli.³⁻⁵ The tumor constitutes 1.1 to 2.4% of all intracranial growths.^{6,7} In the adult, however, hemangioblastomas comprise 7.3% of all primary tumors of the posterior fossa.

Incidence

The peak age incidence is between the ages of 35 and 45 years, with the curve beginning to rise more steeply at 20 years and trailing off between 50 and 60 years of age. Males are more frequently affected than females.

In the cerebellum, paramedian locations were most common, followed by the lateral cerebellar lobes and the vermis. Occasionally the area posterior to the medulla oblongata also was involved. The less involved spinal cord may have an associated syringomyelia.⁷

Associated Lesions

Multiplicity of hemangioblastomas suggests a genetic background of Hippel-Lindau syndrome,^{8,9} especially when associated with angiomas of the retina, non-neoplastic congenital cysts of the pancreas and kidneys, and tumors of the kidneys and

suprarenal glands.

We have had the opportunity, recently, to treat a patient with multiple hemangioblastomas with rather unusual presentations. The renal, pancreatic, or retinal associations were not present, nor were there abnormally high levels of hemoglobin¹⁰ and red blood cells, as have been recorded, probably due to an erythropoietically active substance produced by the tumor.

Report of Case

A 31-year-old man was referred to this clinic with the diagnosis of probable basilar artery aneurysm based on an angiographic study done several days before his admission on February 12, 1972 (Figure 1). His main complaint was unsteadiness and pain in the head and neck of six weeks' duration.

Headache and Neck Pain

The patient had been well until November, 1971, when he began having mild headaches; initially they were described as a "sloshy" feeling inside the head, but later they became a dull persistent discomfort, predominantly bitemporal with radiation to the top of his head. On December 26, 1971, he was awakened by a "falling sensation." When he got out of bed he was quite unsteady; he vomited and noted a sudden sharp pain in his neck, which disappeared within a short time. Over the ensuing two days he felt generally ill with symptoms of

Fig. 1—Right carotid angiogram. Lateral view showing circumscribed vascular mass adjacent and posterior to the supraclinoid portion of the internal carotid artery.

*Mayo Clinic and Mayo Foundation, Rochester, Minnesota.

fatigue and malaise, which he attributed to the flu; however, he felt well enough on December 29 to return to his work. At this time he noted the onset of sharp intermittent pain in his neck, which persisted. This pain increased in severity with any sudden movement, but his neck was not stiff. Intermittent diplopia also was present.

Intermittent Vertigo

The patient had no history of sudden severe headaches or loss of consciousness. He had noted occasional periods of vertigo since December 1971; these were precipitated initially on lowering the head suddenly, but subsequently vertigo would be precipitated on any sudden movement of the head.

On January 3, 1972, the patient consulted his home physician, who prescribed medications for the unsteadiness and aspirin for the neck pain. His symptoms did not subside, however, and on February 2, 1972, he was hospitalized. Cerebral angiography revealed a lesion thought to be a posterior communicating or basilar artery aneurysm. Subsequent to this diagnosis the patient was referred to the Mayo Clinic for surgical treatment. On admission, his systemic review was entirely noncontributory.

Physical examination revealed a well-built man in moderate distress lying still in bed and complaining of a severe headache. His blood pressure was 130/95 mm Hg, pulse 78, and respiration 16.

Neurological Findings

The pertinent clinical findings were horizontal nystagmus increased on gaze to the left; moderate increase in deep tendon reflexes with brisk bilateral extensor plantar responses; slight incoordination in the left upper extremity; and slow, broad-based, and unsteady gait. Neck movement was somewhat limited, especially on extension.

The initial impression at the time of the patient's admission was that he had an indeterminate lesion in the left posterior fossa. The history was more suggestive of a progressive mass than of an acute hemorrhage. The angiogram revealed an opacified mass that appeared to be an aneurysm, but this could not be confirmed on all views of the angiogram.

Fig. 2—Subtraction of lateral view of right carotid angiogram.

Fig. 3—Subtraction of lateral view of left carotid angiogram.

Laboratory Data

The laboratory data on the patient's admission were as follows: hemoglobin 13.1 g/100 ml; hematocrit 38.6%; erythrocyte count 4.09 million/mm³; leukocyte count 8,700/mm³; sedimentation (erythrocyte) rate 50 mm in the first hour; and urinalysis normal. The electrocardiogram and roentgenograms of the chest and head did not show evidence of abnormality. No shift of the midline structures was apparent on the echoencephalogram, and the third ventricle was 6 to 7 mm wide.

Angiography

Angiograms made on February 15, 1972, showed evidence of two vascular masses in and about the sella. One was immediately above and just to the right of the dorsum sellae and was supplied by small branches from the carotid siphon (Figures 2 and 3).

Fig. 4—Anteroposterior view of left vertebral angiogram showing stretching and elongation of vessel over left cerebellar hemisphere.

Fig. 5—Lateral view of left vertebral angiogram showing evidence of mass in left cerebellar hemisphere.

Cerebellar Mass

A third larger but avascular mass was located in the left hemisphere of the cerebellum, causing considerable deviation of the posterior inferior cerebellar artery to the right with stretching of the hemispheric branches (Figure 4). In the center of the large avascular mass was a small vascular nodule, the mass being either a cyst or a hematoma associated with a tumor (Figure 5).

The left cerebellar mass appeared to be responsible for the symptoms and, therefore, the surgeon elected to perform a suboccipital craniectomy and removal of the mass. A cortisone preparation was instituted because of tumor nodules in the region of the sella.

Craniectomy

On February 17, 1972, a suboccipital craniectomy was performed and a cystic hemangioblastoma was removed from the left hemisphere of the cerebellum; it was assumed that the parasellar lesions were similar hemangioblastomas.

Postoperative Course

The patient had an uneventful postoperative course and was dismissed from the hospital on the 14th day after operation. It was deemed advisable to treat the remaining lesions with irradiation to the region of the sella and the interpeduncular fossa. The patient elected to undergo the recommended radiation therapy in his hometown.

Discussion

Intracranial hemangioblastomas¹¹ usually arise in the cerebellum,^{3,12} and the early symptoms are those related to increased intracranial pressure, which results in headache, nausea, vomiting, and papilledema; subsequently, staggering gait with a tendency to swerve to one side, nystagmus, ataxia, diadokokinesis, dysmetria, dizziness, and often ocular rigidity may appear.

References 1-13 will be found on page 1078.

Cause of Symptoms

Dandy² and also Sargent and Greenfield¹² remarked that the symptoms are not due to the usually insignificant tumor but to the increasing size of the cyst. The cyst, by compression of the aqueduct of Sylvius or the fourth ventricle, accounts for the increased pressure and hydrocephalus.

Small Capillary Tumor

The actual tumor is usually small and is incorporated in the wall of a cyst as a mural nodule. The tumor is firm to the touch, and microscopic examination reveals blood spaces and channels of capillaries with endothelial lining in the sinuses within the tumor.

Differential Diagnosis and Prognosis

The differential diagnosis on the clinical findings of cerebellar involvement runs the usual very broad gamut of disease processes. When a solitary hemangioblastoma of the cerebellum is identified, surgical removal of the tumor provides a good prognosis. The recurrence or the development of another tumor from a minute hemangioblastoma, however, is impossible to foretell, although such instances have been reported.¹³

An unanswered question also is the advisability of follow-up angiograms in patients who have had a hemangioblastoma removed from one location. Cerebellar hemangiomas and hemangioblastomas usually are single tumors but they may have multiple lesions demonstrated by angiography at initial study. Symptoms of other lesions may develop later.

The case reported is interesting because of the unusual locations of the multiple lesions.

Summary

Hemangioblastomas usually arise in the cerebellum as solitary tumors. They are frequently associated with other lesions such as pancreatic cysts, polycystic kidneys, and retinal angiomas (von Hippel-Lindau disease). Multiplicity of the tumor is most uncommon. Supratentorial location of the tumor has been found to be extremely rare. We are reporting the case of a patient with multiple hemangioblastomas located in the parasellar region and in the cerebellum. The initial angiographic studies were diagnostically misleading. The cerebellar tumor was responsible for the symptoms and it was surgically removed.

You're never too old to yearn.

When you retire, you'll still want to take vacations.

When you retire, you'll still want to buy new clothes, have an occasional night out, drive a newer car, buy gifts, and be independent.

Will you be able to?

If you have your health there's only one thing that's going to keep you from living the way you want to. Lack of money.

That's where U.S. Savings Bonds come in. You can join the Payroll Savings Plan where you work right now. That way an amount you specify will be set aside from your paycheck and used to buy Bonds. It's an almost painless way to save, and

before you know it, you'll have a sizeable nest egg built up for your retirement years.

U.S. Savings Bonds.

Clinical Path Conference

Lymphadenopathy in a 64 Year Old Female

ROBERT A. GREEN, M.D.* and DAVID W. GAUGER, M.D.†

Dr. M. Khan:

This 64-year-old white woman was admitted on 6/8/72 with a 12 day history of night sweats, malaise, myalgia, headache, and anorexia. She had recently been seen in the E.R. with similar complaints, and this was thought to be a viral infection. She complained that these symptoms were not resolving, and that she wanted admission to the hospital. There was no other contributory history recorded in her chart.

The patient had gallbladder surgery in 1951. She gave a history of arthralgia since 1966, and this was diagnosed as degenerative arthritis. She had a negative workup for collagen disease in the past. The patient was a widow and lived alone. She had three adult children living in Minneapolis. She denied smoking and drinking. There was no history of allergies.

Physical Examinations

BP 130/70, P 92 and regular, T 99.4 and R 18/min. She was a pleasant, cooperative lady with questionable icteric appearance. Head was normocephalic. Eyes showed slight A-V nicking; pupils reacted equally to light and accommodation. Mouth was edentulous and without lesions. Neck was supple; there was no thyromegaly. Multiple, enlarged, firm and nontender lymph nodes were palpable in both anterior and posterior cervical areas bilaterally. She also had bilateral axillary lymphadenopathy. Breasts showed no masses. Lungs were clear to auscultation and percussion. Heart had a regular rhythm, and there were no murmurs. Abdomen showed an old epigastric scar. A nontender liver was palpable 7 cm. below the costal margin. Spleen tip was also palpable. There were no other masses in the abdomen. She had bilateral, inguinal lymphadenopathy. Pelvic examination revealed a cystocele. Rectal examination revealed no masses. Stool was brown in color and guaiac negative. There was no edema of the extremities. Peripheral pulses were good. A right epitrochlear node was palpable. Neurological examination was essentially unremarkable.

Laboratory Data

At the time of admission—hgb. 12.5 gm. %, hct. 38.7%, WBC 13,500 (83% neutrophils, 12% lymphocytes, 4% monocytes, and 1% eosinophils) and platelet count 300,000. Electrolytes were normal, and the remainder of the SMA-12 showed a total protein of 6.4 gm%

with albumin of 2.5 gm%. Calcium 8.7 mg%, alk. phos. 23, total bilirubin 1.1 mg%, BUN 16, blood glucose 97, and SGOT 17. Admission chest Xray showed widening of the mediastinum, which appeared to be consistent with enlarged lymph nodes.

Course

The patient had a low-grade fever. She was investigated for an infectious process. Routine blood and sputum cultures and skin tests (intermediate PPD, mumps, Trichophyton) were negative. In the first week of hospitalization, she had a barium enema and an upper G.I. series done. Barium enema was reported as negative, but the upper G.I. series revealed a large spleen and liver with the spleen causing indentation on the left side of the stomach.

Small bowel follow-through revealed the duodenal bulb to be displaced beyond the normal upper limits from the anterior margin of the vertebral bodies. This was felt to be due to a retrogastric or retroperitoneal mass. She continued to have a low-grade fever, felt weak and anorexic. Her white count ranged between 10,000 and 19,000 with a differential of 60-80% neutrophils. The platelet count remained within normal limits. Hemoglobin remained stable at around 12 gm%. Prothrombin time was 10.8/11.5, PTT was 26.0/35.4. Renal and liver function tests were within normal limits. ESR was 32 mm.

Axillary Node Biopsy

During her second hospital week (on the eighth hospital day) she had a right axillary lymph node biopsy done. The diagnosis was atypical lymphadenitis of undetermined etiology. Bone marrow was hypercellular. Peripheral blood smear revealed normochromic normocytic anemia, leukocytosis and a mild leukemoid reaction. Smear and culture of the lymph node material for fungi, AFB, and Brucella were reported as negative. Blood serology for Brucella, cocci, histo, and blasto was also reported as negative.

Other Diagnostic Procedures

During her third week of hospitalization, she continued to run a low-grade fever. An IVP done at this time showed normal function on both sides; however, there was splenomegaly and hepatomegaly detected. The right kidney appeared to be depressed downward because of an enlarged liver. The following laboratory tests were reported as negative: FANA, Heterophile x 2, viral serology for adenovirus, influenza A & B, and cold agglutinins; VDRL, Sabin-Feldman dye test for toxoplasmosis; complement fixation test for toxoplasmosis,

†Resident in Pathology, Hennepin County General Hospital, University of Minnesota, Minneapolis, Minnesota.

Clinical Path Conference, Hennepin County General Hospital, June 7, 1973.

and serology for Psittacosis and tularemia. Liver biopsy was also reported as normal. A repeat biopsy of the lymph node from the L. cervical area was done, and this again was non-diagnostic, showing only reactive lymphadenitis. The patient continued to feel weak, tired, and anorexic. She was becoming depressed because of the multiple diagnostic procedures being performed on her. During this period, she also developed dependent edema of the legs. Chest Xray revealed evidence of congestive cardiac failure and bilateral pleural effusion. A thoracentesis was done, and the pleural fluid revealed 1600 white cells with 15% neutrophils and 85% monocytes. Gram stain and culture was negative. AFB smear on the fluid was also negative. The fluid had a protein content of 43 mg% and sugar of 105 mg%. The fluid was also negative for tumor cells. A lung scan was done which was reported as negative. A second-strength PPD skin test was also negative. Urine culture grew out more than 100,000 colonies of *E. coli*, and this was treated with Ampicillin.

Events Before Laparotomy

During her fourth hospital week she continued to run a low grade fever. A repeat second strength PPD was negative. On the 22nd hospital day, a lymph node biopsy was performed for the third time. This time a right axillary node was removed. The pathology report read "atypical reactive lymph node." Smear of lymph node imprints were again negative for AFB and fungi. Hgb. was now around 10 gm%, and white cell count was between 13,000 and 20,000. Reticulocyte count was 2.3%. Platelet count remained within normal limits. Serum electrolytes, liver function tests and serum uric acid were within normal limits. It was felt that her lymph nodes had tripled in size since admission. These nodes were nontender and firm in consistency. The liver was palpable 16 cm. below the right costal margin and was firm and nontender. The spleen was also easily palpable. During this period a holosystolic murmur was heard at the RSB in the second intercostal space. Because of this murmur, the possibility of SBE was entertained, and multiple blood cultures were done. All of these blood cultures were reported as negative. The patient seemed to be following a gradual downhill course, and as there was no definite diagnosis established, the patient underwent laparotomy on the 44th hospital day.

Discussion

Dr. Robert Green:

This patient presented with complaints which sounded much like an infection and her early course was thought to be due to viral disease. Her subsequent evaluation included extensive studies to rule out the possibility of infection. With failure of her symptoms to resolve, she was finally admitted to the hospital for a work-up.

The past history, the social history, family history didn't contribute much to her evaluation. The physical examination was notable for generalized lymphadenopathy and hepatomegaly with

moderate enlargement of the spleen. So far, then the staff was presented with the differential diagnosis of generalized lymphadenopathy in an elderly female with fever, and the diagnostic possibilities seemed to be limited to some unusual infectious process or to a malignancy, most likely a malignant lymphoma.

Her laboratory data at the time of admission were not specific. She had a low serum albumin suggesting some albumin synthesizing defect, probably as a result of chronic illness. Xrays showed widening of the mediastinum consistent with her widespread peripheral lymphadenopathy.

Almost every conceivable type of test was done for infection without any significant findings. This included a dye test for toxoplasmosis, presumably considering the possibility of a lymphadenopathic type of toxoplasmosis. One test that was not done was an NBT (nitroblue tetrazolium) test which is sometimes very helpful in distinguishing between bacterial infection and malignancy. It is not helpful in distinguishing viral disease from a malignant process.

Other x-ray studies showed no diagnostic features, but confirmed the presence of a large spleen and liver. Displacement of the duodenal bulb suggested the possibility of a retroperitoneal mass.

A frustrating problem was that of repeated non-diagnostic lymph node biopsies. The bone marrow also failed to show any abnormal disease process, and finally, a biopsy of the enlarged liver was also reported as normal. A liver scan is not reported in the protocol.

She developed signs suggesting congestive heart failure with bilateral pleural effusion. A thoracentesis was done and the findings suggested that the effusion was a transudate but didn't show malignant cells.

Her course was characterized by continuous deterioration and low-grade fever. Bacterial endocarditis was considered because of the development of a systolic murmur and her cardiac problems, but multiple blood cultures were negative. After six weeks, a laparotomy was done. In the absence of findings suggesting malignancy in the kidney or elsewhere, and particularly with the findings of generalized lymphadenopathy and hepatosplenomegaly and despite multiple negative tissue biopsies (nodes, liver) malignant lymphoma was far and away the likeliest diagnosis here and laparotomy the logical next step.

Laparotomy Findings

Dr. David W. Gauger:

At the time of laparotomy, several lymph nodes from the region of the greater omentum were removed. The liver was biopsied and the patient had a splenectomy. The spleen weighed 496 grams. The material obtained at the time of laparotomy was shown to several pathologists. The majority felt this was a malignant process; however, they wanted to be sure that various infectious processes including mononucleosis, rheumatoid arthritis, and granulomatous disease were not present. No Reed-Sternberg cells were identified in the biopsy material. The patient was given the diagnosis of malignant lymphoma, well differentiated, diffuse lymphocytic type with involvement of the spleen and liver.

Staging

Dr. Green:

Had this patient had positive tissue diagnosis on the basis of peripheral node biopsy, it would be clear that she had advanced disease above and below the diaphragm and was symptomatic in the sense that she had fever, anemia and weight loss. Under these circumstances, further staging procedures on which treatment decisions would be based would not be necessary.

Staging of non-Hodgkin's lymphoma is similar to that of Hodgkin's disease except in the use of separate classification for primary extra-nodal disease which has a different prognosis from primary nodal disease.

Stage I disease represents disease limited to a single lymph node group.

Stage II designates disease in which two or more lymph node groups above or below the diaphragm are involved.

Stage III represents disease limited to lymph nodes but including disease above and below the diaphragm.

Stage IV represents disseminated nodal and extra-nodal (visceral, skeletal, marrow, etc.) disease.

Extra-nodal non-Hodgkin's lymphoma includes primary involvement in Waldeyer's ring, such as nasopharyngeal lymphoma, bone, G.I. tract, thyroid, etc. Many of these patients with localized extra-nodal disease have a very favorable prognosis. They are considered separately for therapy, but as in apparently localized nodal disease, to prove that they are localized, they should have additional staging procedures.

In staging non-Hodgkin's lymphoma, a good physical examination is, of course, essential. X-ray studies should include chest X-ray for evaluation of the mediastinum particularly, intravenous pyelogram primarily for evaluation of ureteral deviation by retroperitoneal nodes, and skeletal X-rays, particularly in the presence of skeletal symptomatology.

Laboratory studies in addition to routine blood counts and peripheral blood morphology should include bone marrow aspiration and trephine biopsy, liver function studies and isotope liver scan.

Bone marrow biopsies are positive in a variable percentage, but as high as 40-50 percent in certain types of cases. They are significantly higher in lymphocytic lymphoma than in histiocytic types, more common in advanced clinical stages and

more common in more undifferentiated histologic varieties of lymphoma.

Liver function tests are often not helpful, being quite variable and they cannot be depended on for evidence of liver involvement. Liver scan on the other hand may be quite helpful, probably more so than in Hodgkin's disease.

Lymphangiography

Lymphangiography is still an important study in non-Hodgkin's lymphoma and is recommended in all cases except obvious Stage III and Stage IV patients. The percentage of positives are variable in different series, but a common experience is to find a positive lymphangiogram in a patient who is thought almost certain to have Stage I or II disease before lymphangiography.

Finally, there are a number of cases in whom laparotomy must be done either for diagnosis or because the treatment decision may depend on findings in the abdomen not recognizable by other evaluation. It is particularly helpful in the diagnosis of liver involvement not otherwise suspected. Because localized disease is so much less common in non-Hodgkin's lymphoma, laparotomy will perhaps not need to be done as frequently as in the staging of Hodgkin's disease, but there will still be patients who will change from Stages I and II to Stage III or IV as has been shown by Hanks et al.¹²¹ in a study in which three out of nine clinical Stage I and II patients were changed to III or IV at laparotomy.

Generally speaking, one would tend to use the same criteria in non-Hodgkin's lymphoma as in Hodgkin's disease if other criteria were negative for disease involvement below the diaphragm. Laparoscopic study of the abdomen with needle biopsy under direct vision is a worthwhile procedure in some cases.

Interval History

Dr. Gauger:

The patient was placed on chemotherapy (prednisone and cytoxan) in June of 1972 following the laparotomy and was seen regularly in the Hematology Clinic. The patient was admitted to Hennepin County General Hospital on December 30, 1972 because of a persistent fever of up to 105°F. The patient had last been seen in the Hematology clinic at Hennepin County General Hospital on November 29, 1972, at which time her hemoglobin was 13.1 white count 14,300 and platelets

count was 435,000. She had been continued on her prednisone and cytoxan at that time.

At the time of admission to Hennepin County General Hospital in December of 1972, the patient was felt to be septic, so after doing multiple bacteriological cultures, the patient was started on gentamycin and keflin. The patient received prednisone and cytoxan for the first two days of hospitalization. White blood cell count was 23,000 with 99% neutrophils and the hemoglobin was 11.0 at the time of admission. SGOT was 30, serum protein was 5.8 with an albumin of 2.1, bilirubin 1.2, and BUN 22. Chest Xray revealed widening of the upper mediastinum which was felt to be due either to widening of the ascending aorta or enlargement of the lymph nodes of the anterior mediastinum. Micro-biological examination of the patient revealed *Candida albicans* in the sputum and *Klebsiella Enterobacter* and *Pseudomonas* in the throat culture.

The patient's fever was normal on the fourth hospital day. It was noted at this time that the patient's BUN was beginning to increase and her urine output was decreasing. After eight days of therapy, the gentamycin and keflin were discontinued. On the third hospital day the patient's white count was noted to be 5,200 and this continued to drop to a level of 900 with 100% lymphocytes on the eighth hospital day and the day prior to the patient's death. The hemoglobin at this time was 8.7. On the eighth hospital day, the serum potassium was 5.9, sodium 126, albumin 0.8, and BUN 82. The patient expired on the ninth hospital day.

Autopsy Examination

The deceased was a thin, cachectic, white female with a weight of 105 pounds and a height of five feet four inches. Examination of the head revealed alopecia. There were extensive adhesions present within the abdominal cavity. The spleen was absent. Examination of the thorax revealed bilateral pleural effusions composed of a straw-colored fluid.

There was extensive lymphadenopathy involving the hilar regions of the lungs bilaterally consistent with the x-ray findings. The most prominent mass was anterior to the right main stem bronchus and measured 8 cm. x 4 cm. x 3 cm.

Microscopically this mass consisted of lymphoid tissue which showed marked depletion of the cells and focal areas of necrosis. These changes were

felt to be secondary to the chemotherapy that the deceased had received. Examination of the liver revealed this to be 2,500 grams. Mild fatty metamorphosis was present, as well as centrilobular congestion. The mononuclear cell infiltration of the portal regions in the liver biopsy obtained during the laparotomy were no longer present at the time of autopsy. This depletion of cells was felt to be secondary to the patient's chemotherapy.

Examination of the bone marrow post mortem revealed this to be hypoplastic. The kidneys were symmetrical in size and had a combined weight of 450 grams. Microscopic examination revealed evidence of acute tubular necrosis which was characterized by interstitial edema and a bimorphic appearance of the renal tubules with evidence of regeneration of the distal convoluted tubules.

The heart weighed 320 grams. There was thickening and calcification of the mitral valve. There was no evidence of an active inflammatory process at the time of autopsy. There was evidence of interstitial myocardial fibrosis. There was no evidence of acute myocardial infarction using hematoxylin eosin stain or the Hematoxylin Basic Fuchsin Picric acid stain.

Final anatomic diagnoses:

1. Malignant lymphoma, well differentiated, diffuse lymphocytic type, Stage IV.
 - A. Post chemotherapy for malignant lymphoma.
 - B. Generalized lymphadenopathy with hepatomegaly.
 - C. Post splenectomy.
 - D. Terminal leukopenia and anemia.
 - (1) Hypoplastic bone marrow with pancytopenia.
2. Acute tubular necrosis, kidneys.
 - A. Post gentamycin therapy with evidence of terminal renal failure.
3. Calcified thickened mitral valve.
4. Interstitial myocardial fibrosis.

Treatment

Dr. Green:

Several features of the natural history and histologic characteristics of non-Hodgkin's lymphoma influence treatment decisions and prognosis. Unlike Hodgkin's disease, spread often appears to be by non-contiguous routes in contrast to the orderly progression in most patients with Hodgkin's disease. Skip involvement is common, bone marrow involvement is common and a high percentage of

patients already have Stage IV disease at the outset.

Nodular Vs. Diffuse Pattern

In considering histopathology and its effect on outcome, the nodular pattern offers a better prospect for survival than does the diffuse type of disease and there is a significantly better prospect for patients with more differentiated histology. Well differentiated lymphocytic lymphoma generally has a much better outlook for survival than does poorly differentiated disease or histiocytic lymphoma.

Radiation Therapy

Radiation therapy is the treatment of choice when adequate amounts can be given and when areas of involvement are limited. In proven Stage I and II patients and possibly in some Stage IIIa patients, intensive radiation is the treatment of choice. In primary extra-nodal disease, radiation therapy is certainly the treatment of choice since it really offers a curative prospect. As in Hodgkin's disease, the cure of non-Hodgkin's lymphoma, treated with radiation, is dose related and high dosages in the range of 3,500 to 4,000 rads to the areas of involvement must be given if the intent is to cure.

Stages III and IV

In some patients with Stage IIIa disease, combination treatment may be best, using chemotherapy plus radiation to areas of bulky involvement.

Since perhaps more than half the cases are Stage IIIb and IV, the use of radiation therapy is often not applicable. Total body radiation is now undergoing randomized study with combination chemotherapy in these cases, but the end results of this study are not yet known.

The same general principle applies in chemotherapy of non-Hodgkin's lymphoma as in Hodgkin's disease, namely, that intensive, combined, relatively short-term therapy is more effective than long-term, low dose, single agent therapy. Of the various drugs, Cytoxan is probably the most effective and appears to be more effective than nitrogen mustard in this group of diseases. Similarly vincristine (Oncovin) tends to be more effective than Velban in non-Hodgkin's lymphoma. Single agent therapy results in 10 to 15 percent complete remission with remissions of relatively brief duration.

Because of this lower response and short survival period, combination therapy using Cytoxan, vincristine and prednisone is now the treatment of choice for non-Hodgkin's lymphoma. Treatment is generally given in some type of COP or CVF schedule.

Schedule for Treatment

An example of the former is the schedule used by the Southwest Cancer Chemotherapy Study Group in which Cytoxan is given in dosage of 800 mg./m² intravenously every two weeks, vincristine 2 mg./m² intravenously on day one, and prednisone in dosage of 60 mg./m² by mouth daily for five days. The schedule is repeated every two weeks for six courses. If complete remission is achieved, four additional courses are given at two week intervals. Maintenance appears to prolong duration of remission and survival.

It is important to be aware of the patient's bone marrow reserve in this as well as in any other intensive combined treatment program for lymphoma. Patients with previous intensive radiation and/or intensive chemotherapy will have to be treated less vigorously in terms of lower doses of Cytoxan and vincristine.

The other schedule (CVP) is that of Bagley et al.³ which includes Cytoxan in dosage of 400 mg./m² by mouth daily for five days, vincristine 1.4 mg./m² intravenously on day one, and prednisone 100 mg./m² orally for five days. This course is repeated every 21 days and as in the previous schedule, close attention must be paid to the status of bone marrow reserve.

A 50 to 60 percent complete remission rate is expected with this type of schedule in lymphocytic lymphoma with remission of many months' duration. In complete responders, a high percentage live two years and more.

Of the new drugs, BCNU, a nitrosourea, will produce remissions perhaps in as many as 30 percent of cases refractory to the other drugs, but is probably more effective in Hodgkin's disease than in non-Hodgkin's lymphoma. Bleomycin has produced responses in up to 50 percent of patients and is particularly useful in those with very low bone marrow reserve as a result of previous therapy because Bleomycin is unique in causing little or no myelo-suppression. Adriamycin, a new investigative drug, has produced remission in as high as 60 percent of cases of lymphoma even in patients previously treated with other agents.

Graduation 1973*

J. R. LARSON, M.D.

TODAY IS WITHOUT a doubt a milestone in each of the lives of the graduating seniors in the class of 1973 of the University of Minnesota Medical School. Much has happened since that September day in anatomy when we opened the cadaver cases for the first time.

Orientation, yes, remember orientation; that was when the Dean told us that we were the biggest, the smartest and the best class ever to enroll at the University and I think that most of us even believed him, and maybe still do. We have become somewhat disillusioned, however, since then he has also told every other new class that they were the biggest, smartest and best class.

Yes, a lot has happened since that first day. Some of us have grown our hair longer and some of us have lost what hair we started with. Yes, some good times and some bad. But today first of all, I think that we should stop for a moment and thank those that have helped us along the way. Without them it would have been very difficult. Loved ones, parents, faculty, friends and last but not least, our health profession loans; we thank you.

Today is a milestone, for today we probably know more didactic medicine than we will at any other time in our future careers. This reminds me of the story of the old physician giving advice to his grandson. If you ever get in trouble with the law, secure for your guidance an elderly attorney who is experienced in the ways of the law and wise in the ways of the court, but if ever you get sick, I would advise you to get a physician just out of training, because never again will he know as much as he knows at that moment.

Medical school, I must admit, has been quite an experience. Compared to undergraduate education where college is thought of as a fountain of knowledge where students come to drink; medical school is like drinking out of a fire hydrant. Some describe medical school with the

three P's: petulance, parsimony and pedantry. Others, a minority of course, describe medical school as just purely a dehumanizing experience established solely to subject the students to long periods of stress. Although each of these descriptions has shades of truth, I think medical school was and is much more.

We have come a long way since the Flexner report in 1910 which gave the duty of medical education to the university centers. When you think of it, it is quite a monumental task to educate a diverse student body for diverse roles in the future, not knowing what the future will bring, and only having the tools of present day knowledge that have proven to be outmoded with a half-life of less than seven years. The medical school's job is only vaguely defined as that body which must provide basic knowledge and skills which are common and necessary to all physicians. But with specialization increasing at such a fast rate, the parts seem to be running away with the whole. The faculty, therefore, must be very selective in their presentations. Out of this selectivity, thus evolved the concept of the "core curriculum." The basic core that every physician should know. This then is the "new curriculum." The curriculum designed to eliminate all the ancillary material and to present only the "meat and bones" of medicine. But as we tried to define core, we found out it was a very difficult job. The definition seemed to vary greatly with each group trying to make the definition. But even more vague, now supposedly that we have mastered this elusive core as we are graduating today, is how are we going to apply this to ourselves and to the future practice of medicine.

I think medicine could be compared to an ecologist standing in a river catching debris as it floats by and not going up stream to find out why it is in the river in the first place. Past physicians in our health care delivery system have been involved mainly by necessity in crises care. That is, when the body breaks, you try to fix it. Excellence in the past in our health care system, has been a quantitative judgment. In

*Response given in behalf of Senior Class in Medicine, University of Minnesota, by their President, at the recognition exercises honoring the class, June 8, 1973.

other words, provide more of the same for everyone and hopefully do it at a lower cost.

Health was defined in 1947 by the World Health Organization as the "state of complete physical, mental and social well-being and not merely the absence of disease or infirmity." "The winds of change in health care are the winds of gale force." Americans desire better medical care and want it available to all. No longer is medical care just a social objective but it has become defined as a personal right to be fulfilled. The once quiet and passive consumer now gives urgent voice to new expectations. As Lord Bacon once defined knowledge as being power, we are now and even more so in the future dealing with an increasingly more knowledgeable public from all economic levels. More knowledgeable that is, in the needs and rights of medical care rather than the arts of medicine.

As the goals of our education in trying to define a core curriculum have been quite vague, the boundaries and future goals of health care are vague and very ill-defined. If I may quote Dr. Robert Ebert, dean of the Harvard Medical School, "To provide increased numbers of physicians to rural areas will not meet the need. To do this without other changes will accomplish only what has been achieved in urban areas, a misuse of physicians and a perpetuation of a non-system of medical care." He goes on to say that "it is fruitless for medical schools to experiment with curriculum changes designed to produce general physicians unless they are willing to identify

and study objectively the faults of the system of medical care which we now provide."

There can be no doubt in our mind's eye that the health care delivery system in America will soon change. I think that there can be no doubt that it is to everyone's best interest that we as physicians change with it and because of the vagueness in any system of health care, hopefully lead it. At present with the ever enlarging sense of responsibility for national and individual health the expansion of government's role appears as only a logical consequence. But if I may quote Abraham Lincoln, "the legitimate object of government is to do for a community of people whatever they need to have done but cannot do at all or cannot do as well for themselves by their separate individual capacities. In all that the people can do as well for themselves the government ought not to interfere."

The call and the expectations are there. In the past, we as physicians have not taken a primary role. We have not shown that we could individually expand the system and make it more just.

The public has waited for us, but I do not think that they will wait much longer. Change will be made soon, so before too much longer we as physicians had better become medical statisticians as well as medical physicians and prove and hopefully oversee a new improved health care delivery system which already has been defined as within the rights of society.

Antibiotic Prophylaxis for Bacterial Endocarditis

Necessity or Tradition?

EDWARD L. KAPLAN, M.D.†

THE RECENT PUBLICATION of the American Heart Association's revised recommendations for the prevention of bacterial endocarditis again focuses attention on this problem and the necessity for some of the recommended measures.¹ Bacterial endocarditis still kills.²⁻⁷ On the other hand, it is not a common disease; the average physician rarely sees a patient with bacterial endocarditis. Furthermore, data supporting the use of antibiotic prophylaxis with some of the more commonly performed procedures in dental, surgical and medical practice are not as convincing as many physicians require. Thus, the seriousness of bacterial endocarditis, its relative rarity in clinical practice, and the justifiably questioned efficacy of many methods of antibiotic prophylaxis often render inconsistent the clinical application of some of the principles of bacterial endocarditis prophylaxis.

In considering approaches to this problem the fundamental questions which initially must be answered and then justified before rational implementation of antibiotic prophylaxis to prevent bacterial endocarditis are: which patients and what procedures require antibiotic prophylaxis and, secondly, are there data available to justify these practices?

Although many of the pathogenetic factors which favor the development of bacterial endocarditis are not fully understood, epidemiologic data strongly suggest that the presence of underlying structural defects of the heart or great vessels increase susceptibility to bacterial endocarditis. Vegetations of bacterial endocarditis do occur on normal heart valves, but only rarely in otherwise healthy individuals (in contrast to patients with underlying debilitating diseases). Thus, patients with such diverse conditions as congenital heart disease (with very few exceptions such as uncomplicated atrial septal defects), acquired valv-

ular heart disease (such as rheumatic or calcific valvulitis) or even those few patients who have had a previous bout of bacterial endocarditis on an otherwise normal valve would appear to be included in the group of patients with increased risk.

One other important question to be answered before antibiotic prophylaxis can be justified is: Does *any* bacteremia following a dental or surgical procedure *always* imply susceptibility to the subsequent development of bacterial endocarditis? This, too, is a difficult question to answer for diverse factors such as the age of the patient, the type of underlying heart disease, the species of bacteria involved, and the "dose" of bacteria in the blood stream have all been cited among the many factors which may influence the answer.⁸

It would appear that while bacteremia with certain organisms, such as many gram negative bacteria, may lead to sepsis, certain bacteria (such as *Streptococcus viridans* and *Streptococcus fecalis*) seem to have a greater propensity to cause bacterial endocarditis. Endocarditis prophylaxis is usually directed against organisms of this type.

With these questions in mind, it is the purpose of this paper to briefly review examples of some of the procedures for which antibiotic prophylaxis to prevent bacterial endocarditis have been suggested, pointing out not only the rationale for prophylaxis, but raising questions where prophylaxis seems dictated by tradition rather than by carefully obtained data.

Data regarding the efficacy of antibiotic prophylaxis for bacterial endocarditis, upon close scrutiny, appear to define three broad groups of procedures: First, those conditions from which the best data have been obtained to demonstrate justification for antibiotic prophylaxis; secondly, those situations for which supporting data are available, but because of remaining unanswered questions the need for prophylaxis is still unresolved; and finally those procedures for which there may be adequate theoretical justification for antibiotic prophylaxis, but there are very little, if any, sup-

porting data to assist the physician with clinical decisions.

As an example of the first category, *dental procedures* are undoubtedly among those procedures which require frequent consideration for antibiotic prophylaxis. Most dental procedures—including tooth extraction, periodontal surgery, endodontia, dental prophylaxis and restoration, among others—have been shown to lead to bacteremia.⁹⁻¹¹ The important factor predisposing to bacteremia common to all of these procedures is thought to be gingival bleeding. The occurrence of gingival bleeding is very often difficult, if not impossible, for the dentist or oral surgeon to predict. The fact that there is disagreement in the literature regarding the extent of gingivitis necessary to produce bacteremia does not clarify matters.^{12,13} The multiplicity of bacteria—both aerobes and anaerobes—recovered from blood stream of patients following dental procedures is impressive.¹⁴ An important point, one which places dental procedures in the first group, is that the organism probably most commonly associated with the subacute form of endocarditis, *Streptococcus viridans*, is an important inhabitant of the oropharynx. Furthermore, the proximity of dental procedures to the recognition of bacterial endocarditis has been commented upon numerous times. This suggests at least a temporal, if not a causal relationship between bacteremia—in this case induced by dental procedures—and the subsequent development of bacterial endocarditis. Therefore, it has been recommended that antibiotic prophylaxis be given with *all* dental procedures that are likely to cause gingival bleeding.^{1,15} Contrary to what is often practiced by many physicians and dentists, this recommendation would encompass even routine cleaning of teeth, for gingival bleeding very often is associated with this procedure. The recommendations for antibiotic prophylaxis to prevent bacterial endocarditis would appear to be warranted for children with underlying heart disease as well as for adults. Even though there have been attempts to place children in a separate risk category¹⁶ the available data do not support a difference in the risks for these two groups.^{17,18}

The second category includes surgical procedures for which there are available data to support the use of prophylactic antibiotics to prevent bacterial endocarditis, but aspects of the supporting evidence are considered controversial by some physicians. Two examples seem most ap-

propriate to mention: One, genitourinary tract procedures, is more frequently encountered by the practicing physician than is the other, cardiovascular surgery.

Bacteremia has been documented following *genitourinary tract procedures* ranging from catheterization of the urinary bladder to transurethral resection of the prostate.^{3,19,20,21} What often makes the decision regarding antibiotic prophylaxis to prevent bacterial endocarditis confusing for the physician whose patient is about to undergo a genitourinary tract procedure is the fact that organisms most commonly recovered from blood following these procedures are ones present in urine *prior* to the procedure.²² These are most often gram negative organisms. While these organisms may produce very serious illness such as gram negative shock, they are less commonly mentioned in the literature as a cause for infective endocarditis following urinary tract manipulation. Enterococci, not gram negative bacilli, have been shown to be a frequent cause of bacterial endocarditis following genitourinary tract procedures and it is against these organisms that most commonly used prophylactic regimens are directed.¹

Bacterial endocarditis following *cardiovascular surgery* is feared by surgeons and cardiologists alike. It is not uncommon in the perioperative or postoperative periods, especially following placement of prosthetic heart valves.²³ Data are available which report a decrease in infections—including endocarditis—following cardiovascular surgery with the use of prophylactic antibiotics in the perioperative period.^{24,25} However, conflicting data are also available which show no reduction in the frequency of postoperative infections, when antibiotic prophylaxis is utilized.²⁶ While most cardiovascular surgeons employ antibiotics in the perioperative period, well controlled studies are required to ultimately answer this question.

Since the organisms most frequently responsible for this complication are *Staphylococcus aureus* (coagulase positive) and *Staphylococcus epidermidis* (coagulase negative) antibiotic prophylaxis to prevent bacterial endocarditis in the perioperative period is usually directed toward these organisms.¹ Other organisms such as gram negative bacteria may cause endocarditis following cardiac surgery, but there are no universally effective methods of antibiotic prophylaxis for this group of organisms.

A note should be added here regarding the postoperative management of patients in the years following cardiovascular surgery. It has been suggested that with few exceptions (e.g., secundum atrial septal defect repaired without a patch, and ligated and divided patent ductus arteriosus), all of these patients should continue to receive antibiotic prophylaxis with dental and indicated surgical procedures in the years following cardiovascular surgery just as they did prior to surgery.¹ This appears to be especially true for patients with prosthetic heart valves who remain at high risk.²³ There are, however, no conclusive data available to determine the risk of patients to develop endocarditis following repair of most congenital heart defects. Until more data become available these patients probably should be treated postoperatively as they were prior to surgery.¹

Finally there is the third category of conditions for which sufficient data are essentially nonexistent. A few reports mention bacteremia following such diverse procedures as *vaginal delivery*, *bronchoscopy*, *sigmoidoscopy*, even massage of infected carbuncles.²⁷⁻³⁰ There are no well controlled studies to substantiate the necessity for bacterial endocarditis prophylaxis following these procedures even though, as one might expect, occasional cases of bacterial endocarditis have been reported following these types of procedures.^{3,31} Therefore, largely because of the theoretical risk many physicians feel it unwise to neglect antibiotic prophylaxis. Procedures such as *tonsillectomy and adenoidectomy* and surgery of other infected or contaminated tissues are usually included in the list of procedures for which bacterial endocarditis prophylaxis is recommended for cardiac patients at risk.¹

There are other procedures in this category for which one could also construct a strong theoretical case for the necessity for antibiotic prophylaxis to prevent the occurrence of bacterial endocarditis, but even less satisfactory supporting data exist. For example, bacterial endocarditis has been re-

ported to occur in patients with permanent transvenous pacemakers.³² Indeed one recently reported experimental model for producing bacterial endocarditis requires an indwelling polyethylene tube placed transvenously into the heart.³³ Theoretically, then, patients with hydrocephalus requiring indwelling ventriculoatrial shunts would appear to require protection. Several obstetrical gynecological procedures should be mentioned. Although the exact risk of bacteremia following therapeutic abortion has not been carefully studied, mention has been made of endometritis, parametritis and even sepsis following simple aspiration of the uterus.³⁴ Although a less frequently performed procedure, conization of the uterine cervix is another example of a gynecological procedure which, in theory, might require prophylaxis. Very few helpful data regarding these types of procedures are available in the literature. Because of the absence of well controlled studies, clinical practice varies.

Summary

Many questions regarding the necessity of antibiotic prophylaxis to prevent bacterial endocarditis remain unanswered. These questions are more than academic ones! The morbidity and mortality of bacterial endocarditis cannot be accepted lightly. Although it may be difficult to prove, since more debilitated patients are living longer, physicians and dentists may find themselves faced with this problem more frequently than in the past. The lack of available information upon which to base recommendations for many procedures points out a need for carefully controlled prospective studies. Until these data become available, any set of recommendations for prophylaxis can only hope to present the physician with guidelines based upon what is presently known. It would be best to define the requirements for antibiotic prophylaxis with various dental and surgical procedures rather than to simply rely on tradition.

Postural Screening in an Elementary School

F. PATRICK MALONEY, M.D., M.P.H.* and SHARON HILDEBRANDT, R.P.T.†

POSTURAL PROBLEMS of children are a matter of concern for both professionals and the general public. The Parent-Teachers Association of an Anoka County elementary school evidenced such an interest by their request for postural screening of elementary school pupils. Four physical therapists from Sister Kenny Institute conducted a posture screening of 243 children at the school to assess variations from postural norms. Although this was not undertaken as a formal study, a review of the results provides useful information about the yield of problems that can be expected in a brief screening, the cost of a screening clinic, and the pitfalls that are encountered.

Method

Each child was included on the basis of a written request by a parent. A questionnaire was sent to each of these families and was returned with a request for screening. The questionnaire had two parts: The first requested yes or no answers to a variety of neuromusculoskeletal problems including surgery and prolonged periods of immobilization and chest problems such as heart disease and asthma. Secondly, questions about previous or present needs for orthopedic equipment, braces, or crutches were asked. Explanations were requested for any yes response.

The screening procedure was designed to require less than ten minutes for each child. Body alignment was observed by placing the child behind a see-through grid. The grid had a wooden frame with vertical and horizontal lines of dark thread placed two inches apart in checkerboard fashion. The students were placed in an erect, not relaxed, position behind the grid and toed to markers on the floor for front, back and side determinations.

The grid was used to assist with observations of the alignment and position of the head, spine,

shoulders, scapula, legs, hips, and feet. A checklist of characteristics was used for each child. Specific comments were made regarding forward head, lateral head tilting, kyphosis, lordosis, round back, flat back, hip levels, genu recurvatum, genu valgus, genu varus, foot varus, foot valgus, flattening of the long arch of the foot, tibial torsion, hammer toes, hallux valgus, and scoliosis. Observations of chest deformity or deformity of other bony structures were made. The rib hump sign of spinal rotation was determined by viewing each child from behind throughout flexion at the waist and with the back horizontal. The Trendelenburg test was done on each child.

Each therapist assessed the degree of postural deviations for each characteristic as mild, moderate, or severe. A mild deviation was one which very slightly deviated from the vertical line of gravity in the horizontal and frontal planes. A severe postural deviation was one that was so prominent that it could be observed without the use of the grid. Moderate deviations occupied the range between the two. Any positive rib hump sign was classified as severe. No attempt was made to assess the variability of these assessments between therapists. No photographs, Xrays or measurements were made. Questionnaire data was not validated.

Results were provided to the physician and the parents of each child, as well as to the school. It should be emphasized that diagnoses were not made, but rather, possible problems were identified as a service for the treatment of the child.

Only those children designated moderate and severe were grouped as having problems. Although some variability between therapists exists it is unlikely that the difference is more than one grade of severity. For purpose of parental notification children classified as mild or with a constellation of findings considered mild and those children with no problems were designated as having "no significant variation." Those children with moderate or severe deviations or with lateral or rotational scoliotic-like curves were designated as having "excessive variation." The parents were

*Assistant Professor, Physical Medicine and Rehabilitation, University of Colorado School of Medicine, Denver, Colorado. Formerly, Director of Pediatric Rehabilitation, Kenny Rehabilitation Institute, Minneapolis, Minnesota.

†Staff Physical Therapist, Sister Kenny Institute, Minneapolis, Minnesota.

notified to contact their physician for his opinion about the findings and ascertain what form of follow-up might be desirable. The physicians received written appraisals of all problems regardless of the tabulated designation of mild, moderate, or severe.

Results

Sixty-three percent of the school population was screened. Of the 243 children who were screened, 54.3% were boys and 45.7% were girls. Table 1 shows the percentage age distribution and cumulative percent of those screened. There were 61 problems in 44 children judged by the therapists to be more than of "mild variation." Table 2 shows the general categories of problems.

Positive histories of musculoskeletal problems or of chronic illness of any sort were found in 17.55% of normals, 25.0% of those with mild problems, and 34.15% of those with severe problems. A positive history was considered as one in which any of the questions was answered affirmatively. In the majority of cases, there was no association between the positive history specific to the problem ascertained in the screening. Of the 231 who completed the questionnaire, 14 persons had a positive history with positive findings, 27 had a negative history and positive findings, 23 had a positive history and negative findings, and 167 had no history and no findings.

Proportionally, more boys were examined in the 11 to 13 year age group and more girls in the eight year and under group. Even so, problems were found disproportionately more in boys than in girls in the former group.

The cost of screening is itemized in Table 3.

Discussion

Postural deviations are common in the elementary school age group. Parents and professionals in medicine and education are interested in an economical way to ascertain children with potential problems. Many of the postural deviations are of questionable significance, such as lordosis, mild pronation of the feet, and head tilting. It is not known how many of these children will develop significant discomfort in later life, nor is it clear how many with functional curves will actually develop a structural scoliosis. It is known that pelvic asymmetries of one-half inch or more are associated with back pain in young adulthood and the discomfort is relieved by a shoe lift.¹ In

the elementary age group asymmetries can be corrected by a heel lift.²

Several problems can be noted in the process of carrying out screening clinics. The cost is substantial and, considering the yield, appears to be an inefficient use of skilled professionals (Table 3). The travelling costs would be less at a school closer to the screening facility. The cost of screening if therapists are used from an ongoing program, require either patient treatments to be cancelled or a substitute therapist to be obtained which would further increase the cost. The usual problems of reproducibility of findings and the consistency between therapists' examinations are present. No attempt was made for control of this and in view of the discrepancy in findings between the two therapists who examined the boys and the two who examined the girls this would be essential for any future planning.

Substantially more boys had problems than girls, especially in grades four through six. Only 17 girls were examined in the age group of 11 and over while there were 40 boys in this category. Although a difference in the therapists'

interpretations probably accounts for most of this difference, other factors may be involved. Lateral pelvic asymmetries were found to increase from an incidence of 74.6% in elementary school aged boys to 86.1% in those of junior high school age.³ In the nine-year-old and under group males with problems were not as over represented which would have been expected if clinical interpretation was the only factor. Since boys achieve adult body posture later than girls⁴ the boys may have a wider variation in the normal limits of posture. Secondly, parents may have sent more children with possible problems to be seen. Nothing is known about the posture of the children in the elementary school who were not screened.

The same problems are found in attempts at determining incidence. These have generally used surveys of Xrays or have looked at the spinal Xrays of children who were ascertained after examination for the rib hump sign of spinal rotation.^{5,6} The latter study did not use other physical signs and did not include lateral curves. The incidence of structural scoliotics ascertained in this way by Dr. Ruth Wynne-Davies in 11,000 Edinburgh school pupils is 1.3 per thousand students under eight years of age and 1.8 per thousand of those over eight years.⁶

In the Anoka School, although children eight years of age and under represented 45% of the children examined, this represented only 11.3% of the problems. It would seem that grades one through three could be omitted in any screening program because of this low yield.

More children with a history of neuro musculoskeletal illness or chest disease had postural problems than those without such a history. Even so, positive histories were obtained in 17.55% of ostensibly normal children. Most children with moderate or severe problems and a positive history did not have a history compatible with the problem which was found. Rather it would seem that as a group those with postural difficulties or potential postural difficulties tend to be different in regards to there likelihood of having had a significant chronic illness or period of musculoskeletal impairment. This likelihood was about double that of those with normal screening examinations. The use of a questionnaire did not appear to be of

significant assistance in helping the therapists. In the brief time each had for an examination, the histories were not used and, as noted subsequently, most children with significant problems did not have a positive history for that problem. In addition, such histories are not valid from a diagnostic sense.

It would be more economical for screening to be restricted to the fourth and sixth grades only, with the addition of other selected students. Physical education teachers could be taught to perform such a screening as part of the educational system's offering. An experienced therapist could supervise such a program. Because of the variability in the examinations of therapists, it is even more important that adequate attention be paid to standardizing the physical education instructors in regards to reproducibility of findings of each screener and the reliability of results between screeners.

The actual mechanics of doing this screening along with the written requests from the parents and post screening notification of parents and physicians appears to work fairly well and should be incorporated in any contemplated screening program.

Summary

Four physical therapists conducted a postural screening clinic for 243 elementary school age children. The problems inherent in conducting this were discussed. The cost appears prohibitive for the general use of such screening clinics.

Histories taken from questionnaires were not valuable in assisting the therapists. The yield in problems ascertained in the first three grades is not sufficient to warrant general screening for this group. It was feasible to screen children in an examination of less than ten minutes.

A feasible and economic alternative using physical education instructors under the supervision of a physical therapist was discussed.

Acknowledgment

We wish to acknowledge Mr. H. Eugene Baland, Principal of Lynwood Elementary School; Ann Lindgren, RPT; Gail Dahl, RPT; DeLeres Ullstrom, RPT; and the school nurses Liz Frigstad and Phyllis Haas for their assistance in organizing and carrying out the posture screening sessions.

Guidelines for the Performance of Abortions

as adopted by the
Minnesota State Medical Association, May, 1973

Public Education

EDUCATION ABOUT abortion procedures and services is the responsibility of all health agencies and professionals concerned about the care of women. A variety of agencies should assume a leadership role in making the following essential facts known to the public.

1. Abortion should always be a matter of free personal choice and should not be provided under coercion. Information about alternatives to abortion such as maternity homes, adoption, etc., should be made available.
2. Abortion should not be relied upon as a primary means of fertility control. Contraception or sterilization are preferable to abortion as methods of preventing unwanted births.
3. The symptoms and signs of pregnancy should be widely disseminated so that those wishing to terminate a pregnancy may seek assistance at the earliest stage of pregnancy possible; it should be stressed to both doctor and patient that both risks and costs are lower, when abortion is sought early in pregnancy—specifically in the first trimester.
4. The diagnosis of pregnancy should be confirmed prior to abortion through the performance of a physical examination and, if necessary, a laboratory test for pregnancy. At present screening tests for pregnancy which are available over drugstore counters must not be relied on as substitutes for pregnancy tests performed in laboratories. Abortion must be performed by licensed physicians.
5. Information regarding follow-up care and counseling, including specific places or persons to contact for medical services essential to the prevention or discovery of post-abortion complications or emergencies should be provided.
6. Educational literature on abortion should:
 - A. Be readily obtained.
 - B. Stress that abortion is a matter of free choice and should be entered into without coercion and with full knowledge of all available alternatives.
 - C. Specify agencies or individuals who can provide further information, counseling and service.
 - D. Discourage individuals from seeking illegal abortions.

E. Stress the importance of medical follow-up after an abortion.

F. Emphasize the desirability of contraception instead of abortions to avoid unwanted pregnancy. Facts concerning sterilization should also be made available.

G. Physician's fees for abortion should be comparable with his fees for a similar surgical procedure.

H. Physicians should have information about public assistance programs, other insurance coverage, and other abortion facilities.

Referral

Abortion referral services should be available through a variety of sources:

1. Referral should be made only to physicians and facilities which meet the provisions contained in these Guidelines.
2. Before referrals for abortions are made the patient should be seen and examined by a physician to determine whether the patient is pregnant and the estimate of duration of gestation.
3. Medical associations should encourage and assist their memberships in the establishment of appropriate referral relationships. All professional associations should continue to emphasize adherence to traditional ethics.
4. Physicians should be encouraged to establish referral relationships with community counseling, social service agencies and mental health centers.

Counseling Services

Physicians should make counseling services an integral component of their abortion programs. Counseling services should be readily available to all women seeking abortion services. Each abortion service shall provide abortion counseling if desired by the woman, as well as a referral to clergy, social services or other appropriate mental health services when needed. Three basic principles of abortion counseling are that:

1. Specialized professional consultation, such as psychiatric, social service, psychological, religious, etc., should be available, not mandatory.
2. Be supportive and non-judgmental regardless of the circumstances of the pregnancy.
3. That it be an educational experience.

The aims of abortion counseling are:

1. To aid the woman in making a decision about

ABORTION GUIDELINES

her pregnancy.

2. To help her implement the decision.
3. To assist her in controlling her future fertility.

The manner in which counseling is carried out plays a major role in determining whether the woman is protected against exploitation and is treated in a safe, humane, and dignified manner. The following standards are recommended to accomplish this:

1. Non-judgmental and supportive explanation of all alternatives available including social, medical, and financial assistance where available.
2. Counseling should serve, when appropriate, to simplify and expedite the provision of abortion services. It should not impose unnecessary medical risk by delaying the obtaining of these services.
3. Specialized professional consultation, such as psychiatric, social service, psychological, religious, etc., should be available, but not mandatory.
4. Preventive measures including contraception and/or sterilization, with specific plans for followup should be discussed with each woman.

Factors to consider in counseling:

1. Pregnancy termination may be part of the problem, not just the solution. The fact that a woman has become pregnant may be a *symptom of underlying psychological conflicts*. Opportunities should be available for further counseling.
2. Physicians are encouraged to acquire counseling techniques.

Medical Surgical Guidelines

A medical history shall be obtained and a physical examination shall be performed including a pelvic examination.

The following laboratory tests should be performed on every abortion patient:

- Hematocrit or Hemoglobin
- White Blood Count and differential
- Urinalysis
- Rh Typing—specimen retaining in the event of cross-matching tests for transfusion if required and for the possible administering of Rh vaccine.
- Gonorrheal Cultures are recommended
- Papanicolaus Smears are recommended when indicated
- Serological test for syphilis

During the first trimester abortion facilities should have the following available:

- a. laboratory facilities (hemoglobin, Rh, urinalysis, pregnancy testing, Pap smear, VD testing)
- b. blood bank
- c. anesthesia
- d. emergency facilities

- e. transportation to a hospital, if necessary
- f. pathological examination—examination of the contents of the uterus and report to the State Board of Health
- g. family planning information and materials
- h. two week post-abortion examination

During the second trimester abortions should be performed:

- a. under conditions enumerated above
- b. only in a hospital licensed by the state or in an equivalent facility

Termination of pregnancy during the period of viability is justifiable only to save the life of the mother or fetus. Reasonable effort shall be made to deliver a liveborn child. Termination of pregnancy should be performed only under conditions listed above.

A pathological examination by a pathologist should be made of tissues removed during an abortive procedure. Hospital clinics should comply with the prevailing policies of that hospital and the hospital licensure requirements in the handling, examination and disposition of such tissue.

Essential Therapy for Rh Negative Patients— Anti Rh immune globulin therapy should be given to all Rh negative patients within 72 hours of completion of the abortion procedure, when appropriate to the patient's future childbearing potential.

If for any reason a patient refuses such therapy, this refusal should be noted by the physician in the clinical record, and documented and supported by the patient's signature on appropriate release forms to protect the physician and the facility from future liability involving subsequent pregnancy problems.

Facilities

Abortions performed in the first trimester may be done in the following types of facilities:

*Licensed Hospital**

A hospital is an institution licensed by the State Department of Health adequately and properly staffed and equipped: providing services, facilities and beds for the reception and care for a continuous period longer than 12 hours for one or more non-related persons requiring diagnosis, treatment or care for illness, injury or pregnancy; and regularly making available clinical laboratory services, diagnostic x-ray services, and treatment facilities for (a) surgery or (b) obstetrical care or (c) other definitive medical treatment of similar extent. The following are not "hospitals" within these regulations: diagnostic or treatment centers, physicians' offices or clinics, and facilities for the

*Minnesota Statutes and Regulations of the Minnesota State Board of Health for Licensing Maintenance and Operation of Hospitals, 1955.

ABORTION GUIDELINES

foster care of children licensed by the Commissioner of Welfare.

Affiliated Facility Abortion Service

Is a facility organized for the primary purpose of providing abortion service which is located within a total transport time of ten minutes from a licensed hospital with which such service has a written affiliation agreement for the treatment of its patients. Total transport time means the total elapsed time between the diagnosis, at an affiliated abortion service, of a complication requiring emergency care and the transfer of both the patient and the responsibility for the patient's care to appropriate medical personnel at a hospital. It is desirable and recommended that abortion services provided in the offices of a physician or group of physicians should meet these guidelines.

Operating Requirements

Licensed Hospital

Shall meet the requirements of the State Board of Health Regulations previously cited including Section 4231:

Surgical Department

Areas to be Provided. All hospitals providing for the surgical care of patients shall have an operating room or rooms, scrub-up facilities, clean-up facilities and space for the storage of surgical supplies and instruments. The surgical suite shall be located to prevent routine traffic through it to any other part of the hospital.

Operating Room. The operating room shall be of a sufficient size to accommodate the personnel and equipment needed.

Illumination. There shall be satisfactory illumination of the operative field as well as general illumination.

Sterilizing Facilities. Adequate work space, sterilizing space and sterile storage space shall be provided. Sterilizers and autoclaves of the proper type and necessary capacity for the sterilization of utensils, instruments, dressings, water and other solutions shall be provided and maintained in an operating condition. Special precautions shall be taken so that sterile supplies are readily identifiable as such and are completely separated from nonsterile supplies.

Affiliated Facility Abortion Service

Admission and Examination Facilities—for registration, counseling, medical evaluation, examination and referral, equipped with suitable furnishings

and accommodations, including waiting and dressing rooms and other appurtenances for the privacy, physical comfort and convenience of patients and personnel. Sufficient, suitably equipped examining rooms shall be provided for the daily caseload. Nothing contained herein shall prohibit registration, interviewing, history-taking, medical examination and appropriate referral from being conducted in an existing physician's office or medical facility.

Procedure Room—All rooms in which abortions are performed shall be adequately equipped, supplied and staffed and shall include the following in addition to the instruments and equipment needed for the performance of abortions:

(a) Anesthesia equipment and such other equipment as is necessary to treat patients for hemorrhage, shock, cardiac arrest, and other emergencies.

(b) An adequate supply of drugs, plasma expanders and parental fluids immediately available at all times with appropriate refrigeration equipment therefor.

(c) Dressing room and scrub-up facilities which are suitably located.

(d) A utility room with facilities for sterilization of supplies, except in an abortion service which receives sterile supplies from a central supply service.

(e) The operating facilities and equipment shall be constructed and maintained so as to be free from sanitary hazards and safety hazards.

(f) Environmental controls to prevent infection, including the control of personnel and patient traffic, shall be maintained in the operating facilities.

Recovery Room—An adequately sized and separate recovery room or rooms in proximity to the operating facilities shall be provided. The recovery room shall contain adequate suction, oxygen resuscitative, and other related equipment. Such room shall be staffed by qualified nursing personnel. An appropriate number of recovery beds and/or rooms shall be provided to insure an adequate length of recovery time as determined by the physician for the recovery of each patient.

Laboratory Facilities—The affiliation agreement shall include provision for use in the hospital of those facilities required in these guidelines. However, the affiliated abortion service shall have on its premises such facilities as are necessary for clinical tests specified in the agreement. An adequate supply of drugs, plasma expanders and parental fluids shall be available at all times under appropriate storage.

ABORTION GUIDELINES

Elevators—any building of more than one story in height and of which an abortion service is a part should be provided with an elevator for the use of non-ambulatory abortion patients. The elevator shall be of sufficient size to accommodate a standard stretcher.

Transportation—An affiliated abortion service should have immediately available organized transportation capable of insuring that a patient requiring emergency care will be transported to the affiliated hospital within the total transport time of ten minutes. Patients should be accompanied by attending personnel when being transported.

Affiliation Agreement—should make available all hospital facilities and services.

Operative and Post Operative Guidelines

Abortions on patients with a gestation up to and including twelve weeks as determined by the physician may be performed on an ambulatory basis if the patient's medical condition permits.

The following patients shall be treated on an inpatient basis for the abortion:

- A. Patients pregnant more than twelve weeks as determined by the physician;
- B. Patients having medical, surgical, gynecological or psychiatric indications.

Patients should receive the following post-operative care:

- A. Patients whose pregnancy was terminated on an ambulatory basis shall be observed in the abortion service for a reasonable length of time as determined by the physician to ensure that no immediate post-operative complications are present and thereafter such patients may be discharged if their course has been uneventful;
- B. Patients in whom any adverse condition exists or in whom a complication is known or suspected to have occurred during or after the performance of the abortion should be followed carefully in a manner determined by the physician.

Written instructions should be issued to all patients in accordance with the rules of the physician in charge of the abortion service and shall include the following:

- A. Symptoms of complications to be looked for;
- B. Activities to be avoided;
- C. Specific telephone number to be used by the patient should any complication occur or question arise;
- D. Date for follow up visit after the performance of the abortion, which should be scheduled within two weeks.

The patient should receive information on the availability of family planning services when desired. Family planning services should be offered

with the consent of the patient prior to leaving the abortion service.

Accessibility

Abortion services should be as reasonably available to those desiring them as are other surgical procedures.

Quality Control

Establishment of internal quality review mechanisms is strongly encouraged using a team approach including the administrator, physician, registered nurse and counselor. Recommended areas for such evaluation include:

Personnel	Discharge Procedures
Physical Plant	Follow up Procedures
Intake Procedure	Emergency Procedures
Preoperative Management and Procedures	Records
Operative Procedures	Communication with Referring Agency
Recovery Procedures	Financial Practices

Abortion Services Personnel

The following are recommended qualifications and duties for the various personnel involved in the delivery of abortion services and are intended to apply to all such services, regardless of the type of facility in which they are provided. These factors should be considered in obtaining personnel or assigning of staff to an abortion service.

Medical

Medical Director—a physician licensed under Minnesota Law, preferably one who is eligible for or certified by the American Board of Obstetrics and Gynecology. Further, it is recommended that he/she be capable of providing medical supervision of the abortion services in their entirety.

Duties. Establishes, implements and is responsible for written medical policy and standards.

Designates a licensed physician or physicians whom he/she deems qualified to supervise directly the care of all patients undergoing abortion, including their post-operative care and follow-up.

Provides consultation to the staff as necessary.

Physicians—must be licensed under Minnesota Law, and appropriately qualified by training and/or experience to perform abortion services. It is further recommended that the physician hold a staff position in a licensed hospital and has demonstrated competence in the performance of abortion procedures.

Chief Nurse—a currently licensed registered nurse.

Duties

A. Develop, implement and be responsible for

ABORTION GUIDELINES

written nursing policies, standards and services.

B. Supervise and direct the nursing personnel and services.

C. Provide for nursing service at all time.

Other Personnel—Registered nurses, licensed practical nurses, student nurses, practical nurses, attendants and other ancillary personnel assigned to give nursing care in an abortion service shall be adequately trained in observational and emergency techniques for pre-operative and post-operative care of abortion patients and shall be supervised by registered nurses.

Administrative Personnel

Administrator—an administrator may be a non-medical administrator, qualified by education and/or experience. He/she is employed to manage the business and administrative aspects of a free standing abortion service. In hospitals administration services should be provided through the existing Department of Administration.

Duties. (A) Develops and is responsible for implementing all administrative policies. (B) Provides for all necessary support services including reception, admitting, counseling, clerical, house-keeping, accounting, reporting, etc. to assure proper reception and admitting procedures, to maintain required records, compile necessary statistics and execute required reports, as well as to conduct the business functions of the facility in an efficient and adequate manner.

Counselors

Counselors should be knowledgeable by training and/or experience and should be capable of providing the counseling services recommended in these guidelines.

Reporting and Records

Reporting of abortions is essential to planning for, providing, and improving maternal health and family planning services. All confirmed abortions shall be reported. The Minnesota Department of Health will assume the responsibility for collecting abortion reports.

The following records and reports are recommended for inclusion in the abortion reporting system. The facilities' administrators should maintain all such records and reports, and be respon-

sible for conveying them to appropriate agencies. Reports should identify individual patients and physicians in the manner required by the State Board of Health.

1. Reports submitted to the Minnesota Department of Health within fifteen days of the abortion will include:

- Facility Name and Address
- Date of Abortion
- Residence
- Age
- Marital Status
- Education
- Number of previous pregnancies
- Number of living children
- Number of previously induced abortions
- Date last live birth
- Date last normal menses began
- Estimate duration of gestation documented by weight and length
- Medical Condition of Woman and fetus (including indications for abortion)
- Operation procedure
- Sterilization
- Complications

2. **Abortion Service Records**—Each facility shall maintain and ensure the confidentiality of clinical records for each patient admitted to the facility. The clinical record for each patient will include the following:

- A. Personal identification
- B. Date of abortion
- C. Gestational size
- D. Age of woman
- E. Technique of abortion
- F. Number of prior pregnancies
- G. Number of prior deliveries
- H. Number of prior abortions, induced and spontaneous
- I. Consent form
- J. Medical history
- K. Report of physical examination
- L. Report of diagnostic findings
- M. Diagnostic and therapeutic orders
- N. Reports of all medical procedures including weight and length of conceptus and counseling performed
- O. Conclusions
- P. Plans for and results of follow up
- Q. Records of post abortion examinations and treatment
- R. Blood type and Rh
- S. Use of Rh immune globulin when indicated

Minnesota State Medical Association

121st Annual Meeting of the Minnesota State Medical Association will be held in Duluth, May 16 and 17, in the Duluth Arena-Auditorium.

Recommendations[†] on Combination Live Virus Vaccines

American Academy of Pediatrics

Committee on Infectious Diseases

In the September 15, 1971 AAP Newsletter sent to Academy members, the Committee on Infectious Diseases of the American Academy of Pediatrics stated its recommendations on the use of combination live virus vaccines. After a careful review of available data, the committee concluded that:

- "This information indicates that the products are both safe and effective when used as directed."
- The vaccine "...can, therefore, be recommended with the obvious advantages of reduction in the number of injections for any given child and a concomitant decrease in the required visits to a physician's office or clinic."

[†]For complete text of both recommendations see your MSD representative or write to Professional Service Dept., Merck Sharp & Dohme, West Point, Pa. 19486.

United States Public Health Service

Advisory Committee on Immunization Practices

In the April 24, 1971 issue of *Morbidity and Mortality Weekly Report*, the Advisory Committee on Immunization Practices of the United States Public Health Service presented recommendations on the use of combination live virus vaccines. The committee stated that:

- "Data indicate that antibody response to each component of these combination vaccines is comparable with antibody response to the individual vaccines given separately."
- "There is no evidence that adverse reactions to the combination products occur more frequently or are more severe than known reactions to the individual vaccines (see pertinent ACIP recommendations)."
- "The obvious convenience of giving already selected antigens in combined form should encourage consideration of using these products when appropriate."

M-M-R^{*}

(MEASLES, MUMPS AND RUBELLA VIRUS VACCINE, LIVE | MSD)

Single-dose vials

M-M-R, given in a single injection, fits easily into your routine immunization program for well babies.

Given at age 12 months, M-M-R provides for vaccination early in life against measles, mumps, and rubella.

MSD suggested immunization schedule for well babies

Age	Vaccine(s)
2 months	DPT (diphtheria-pertussis-tetanus) Oral poliomyelitis vaccine (triple)
3 months	DPT ¹
4 months	DPT Oral poliomyelitis vaccine (triple)
6 months	Oral poliomyelitis vaccine (triple)
12 MONTHS	M-M-R (MEASLES, MUMPS AND RUBELLA VIRUS VACCINE, LIVE, MSD)

¹This vaccination may be given at 3 months, 5 months, or at 6 months, depending on your preference or on the condition of the child.

Since vaccination with a live virus vaccine may depress the results of a tuberculin test for four weeks or longer, the test and the vaccine should not be given during the same office visit.

^{*}Trademark of Merck & Co., Inc.

For a brief summary of prescribing information, please see following page.

M-M-R

(MEASLES, MUMPS AND RUBELLA VIRUS VACCINE, LIVE | MSD)

Single-dose vials

Contraindications: Pregnancy or possibility of pregnancy within three months following vaccination; infants less than one year old; sensitivity to chicken or duck, chicken or duck eggs or feathers, or neomycin; any febrile respiratory illness or other active febrile infection; active untreated tuberculosis; therapy with ACTH, corticosteroids, irradiation, alkylating agents, or antimetabolites; blood dyscrasias, leukemia, lymphomas of any type, or other malignant neoplasms affecting the bone marrow or lymphatic systems; gamma globulin deficiency, i.e., agammaglobulinemia, hypogammaglobulinemia, and dysgammaglobulinemia.

Precautions: Administer subcutaneously; do not give intravenously. Epinephrine should be available for immediate use should an anaphylactoid reaction occur. Should not be given less than one month before or after immunization with other live virus vaccines, with the exception of monovalent or trivalent poliovirus vaccine, live, oral, which may be administered simultaneously; vaccination should be deferred for at least three months following blood transfusions or administration of more than 0.02 ml immune serum globulin (human) per pound of body weight, or human plasma.

Due caution should be employed in children with a history of febrile convulsions, cerebral injury, or any other condition in which stress due to fever should be avoided. The physician should be alert to the temperature elevation which may occur 5 to 12 days after vaccination.

Excretion of the live attenuated rubella virus from the throat has occurred in the majority of susceptible individuals administered the rubella vaccine. There is no definitive evidence to indicate that such virus is contagious to susceptible persons who are in contact with the vaccinated individuals. Consequently, transmission, while accepted as a theoretical possibility, has not been regarded as a significant risk.

Attenuated live virus measles, mumps, and rubella vaccines, given separately, may temporarily depress tuberculin skin sensitivity; therefore, if a tuberculin test is to be done, it should be scheduled before vaccination, to avoid the possibility of a false negative response.

Before reconstitution, refrigerate vaccine at 2-8 C (35.6-46.4 F) and protect from light. Use only diluent supplied to reconstitute vaccine. If not used immediately, return reconstituted vaccine to refrigerator at 2-8 C (35.6-46.4 F), and discard after eight hours.

Adverse Reactions: To date, clinical evaluation has not revealed any adverse reactions peculiar to the combination. The adverse reactions that occurred were limited to those that have been reported previously for the component vaccines.

Fever, rash; mild local reactions such as erythema, induration, tenderness, regional lymphadenopathy; parotitis; thrombocytopenia and purpura; allergic reactions such as urticaria; arthritis, arthralgia, and polyneuritis.

Occasionally, moderate fever (101-102.9 F); less commonly, high fever (above 103 F); rarely, febrile convulsions.

Encephalitis and other nervous system reactions that have

occurred very rarely with the individual vaccines also occur with the combined vaccine. Experience from more than 44 million doses of all live measles vaccines given in the U.S. by mid-1971 indicates that significant central nervous system reactions such as encephalitis occurring within 30 days after vaccination, have been temporally associated with measles vaccine approximately once for every million doses. In no case has been shown that reactions were actually caused by vaccine. The Center for Disease Control has pointed out that "a certain number of cases of encephalitis may be expected to occur in a large childhood population in a defined period of time even when no vaccines are administered. A survey conducted in New Jersey in 1968 showed that 2.8 cases of encephalitis (of unknown cause) occurred per million children, ages 1-9 years, in a 30-day period." However, the Center for Disease Control has analyzed the reported reactions following measles vaccines and pointed out that "the clustering of cases in the period 6 through 13 days after inoculation as well as the recovery of measles virus (probably the vaccine strain) from the CSF of one patient do suggest that some of these cases may have been caused by the vaccine." The risk of such serious neurological disorders following live measles virus vaccine administration remains far less than that for encephalitis with measles (one per thousand reported cases).

Transient arthritis, arthralgia, and polyneuritis are features of natural rubella and vary in frequency and severity with age and sex, being greatest in adult females and least in prepubertal children. Such reactions have been reported with live attenuated rubella virus vaccines. Symptoms relating to joints (pain, swelling, stiffness, etc.) and to peripheral nerves (pain, numbness, tingling, etc.) occurring within approximately two months after immunization should be considered as possibly vaccine related. Symptoms have generally been mild and of no more than three days' duration. The incidence in prepubertal children would appear to be less than 1% for reactions that would interfere with normal activity or necessitate medical attention.

How Supplied: Single-dose vials of lyophilized vaccine containing when reconstituted not less than 1,000 TCID₅₀ (tissue culture infectious doses) of measles virus vaccine, live, attenuated, 5,000 TCID₅₀ of mumps virus vaccine, live, and 1,000 TCID₅₀ of rubella virus vaccine, live, expressed in terms of the assigned titer of the FDA Reference Measles, Mumps, and Rubella Viruses, and approximately 25 mcg neomycin, with a disposable syringe containing diluent and fitted with a 25-gauge, 3/8" needle. Also in boxes of 10 single-dose vials nested in a pop-out tray with a separate box of 10 diluent-containing syringes.

In Memoriam

MILTON ABRAMSON, M.D.

Dr. Milton Abramson, 68, Minneapolis obstetrician and gynecologist, died November 5. Born in Floodwood, Minnesota, Dr. Abramson received his medical education from the University of Minnesota Medical School.

He was a member of the American Medical Association, the Minnesota State Medical Association and the Hennepin County Medical Society.

He is survived by his wife, Ruth, daughter, Mrs. Martin Barke, and sons, Dr. Michael Abramson of San Francisco and Dr. Burton Abramson of Hopkins.

CLAUDE C. KENNEDY, M.D.

Dr. Claude C. Kennedy, 88, Minneapolis surgeon, died November 3. He was a graduate of Marquette University Medical School.

On the surgical staffs of both Asbury and Swedish Hospitals for many years, Dr. Kennedy was also a member of the American Medical Association and the Hennepin County Medical Society, and a 50 Club and Life Member of the Minnesota State Medical Association.

In 1966, he was appointed to the staff of the Mayo Clinic, Rochester, as a consultant in internal medicine.

Dr. Kennedy is survived by his daughter, Mrs. Lindsay Booth of Radlands, California.

FRANK H. KRUSEN, M.D.

Dr. Frank H. Krusen, 75, authority on physical medicine and rehabilitation who founded the Mayo Clinic's Department of Physical Medicine and Rehabilitation, died September 16. He retired from the Clinic in 1963 to become a professor at Temple University School of Medicine, Philadelphia. Later he was adviser to the Division of Physical Medicine at Tufts School of Medicine in Boston, until he retired a few years ago.

His education was obtained at Jefferson Medical College in Philadelphia. He served as president of the Sister Kenny Foundation and Director of the Kenny Rehabilitation Institute in Minneapolis from 1960 to 1963 and was a former president of the American Academy of Physical Medicine, and former president of the Minnesota State Board of Health. He held countless honorary degrees from medical universities and societies. The People's People Eisenhower Award was presented to him by resident Nixon.

He is survived by his wife, Margaret, and two daughters, Mrs. Robert Hart and Janice Krusen.

EDWIN G. HUBIN, M.D.

Dr. Hubin, 79, a practicing physician in Sandstone and in northern Pine County for the past 36 years, died September 4.

He was active in his community and in medical circles and was instrumental in the building of the Pine County Memorial Hospital. In addition, he was a member of the American Medical Association, the Minnesota State Medical Association and the East Central Minnesota Medical Society.

Dr. Hubin is survived by his three sons, Allen, Edgar and Wilbert.

VILHELM MANUEL JOHNSON, M.D.

Dr. V. M. Johnson, 59, Dawson physician, accidentally drowned while on a fishing outing, October 3. He had been serving as a member of the Judicial and Insurance Liaison Committees of the Minnesota State Medical Association at the time of his death.

He had served as a Director for Blue Cross and Blue Shield since 1966 and was a charter member of Blue Cross; was affiliated with the American Medical Association, the Minnesota State Medical Association and the Camp Release District Medical Society. In addition he was a Fellow in the American Academy of Family Physicians.

Dr. Johnson is survived by his wife, Margaret, daughter Marsha, and three sons, Kimball, Reed and Todd.

RICHARD N. JONES, M.D.

Dr. Richard N. Jones, 89, St. Cloud surgeon, died September 7. A native of Gomer, Ohio, Dr. Jones received his medical degree from the University of Chicago and Rush Medical College in 1914. After his retirement in 1968, Dr. Jones was active in voluntary service with the Red Cross Blood Bank in St. Cloud.

He was a member of the Stearns-Benton Medical Society, the American Medical Association, the American Academy of General Practice and the American College of Surgeons, and a 50 Club and Life member of the Minnesota State Medical Association.

Dr. Jones is survived by his wife, Marie, daughter, Ellen, and son, Dr. Richard N. Jones, Jr. of Portland.

IN MEMORIAM

JOHN P. McDOWELL, M.D.

Dr. J. P. McDowell, 95, former St. Cloud physician, died September 17. He had practiced medicine in St. Cloud for 57 years and was Stearns County Coroner for eight years.

A 50 Club and Life member of the Minnesota State Medical Association, Dr. McDowell was also a member of the American Medical Association and the Stearns-Benton County Medical Society.

Dr. McDowell is survived by his daughters, Mrs. Lloyd Peters and Mrs. Richard Jones.

WILLIAM A. HANSON, M.D.

Dr. William A. Hanson, 80, a Rochester native and a Minneapolis physician, died September 22. He was closely associated with the University of Minnesota athletics, and co-founder of the University of Minnesota Medical Foundation. His action as a lobbyist was the key to the Minnesota Legislature's support of \$5 million for the Mayo Memorial Building, a part of the University's Medical Centers.

Dr. Hanson was a member of the Minnesota Academy of Medicine, the American Medical Association, the Hennepin County Medical Society and a 50 Club and Life Member of the Minnesota State Medical Association.

He is survived by his wife, Charlotte, a son, William, and a daughter, Mrs. W. Carpenter.

SAMUEL G. BALKIN, M.D.

Dr. Samuel G. Balkin, 67, Minneapolis surgeon, died October 15. He was a former faculty member at the University of Minnesota Medical School, head of Plastic Surgery at Hennepin County General Hospital, past president of the American Society of Maxillofacial Surgery, former chief of staff at Mount Sinai Hospital, and a member of the American Medical Association and the Hennepin County Medical Society. Dr. Balkin was an associate member of the Minnesota State Medical Association.

Born in Minneapolis, Dr. Balkin obtained his medical education at the University of Minnesota.

He is survived by his wife, Florence, two daughters, Mrs. Douglas Preston and Mrs. Donald Kirschner.

MAX E. SCHOTTLER, M.D.

Dr. Max E. Schottler, 70, Minneapolis physician, died October 2. Born in Dexter, Minnesota, his medical education was obtained at the University of Minnesota.

He was a member of the American Medical Association, the Minnesota State Medical Association and the Hennepin County Medical Society.

CHARLES G. UHLEY, M.D.

Dr. Charles Gordon Uhley, 69, formerly with the Northwestern Clinic in Crookston for many years, died August 27. Born in Slayton, he graduated from Macalester College in St. Paul and taught school in South Dakota. After a few years of teaching, he enrolled at the University of Minnesota and graduated from Medical School in 1933.

He was surgeon for the Great Northern Railroad until his retirement and was on the staff of both Bethesda and St. Francis Hospitals in Crookston. Dr. Uhley was

a member of the American Medical Association, the Minnesota State Medical Association, the Red River Valley Medical Society, the American College of Surgeons, the Minnesota Surgical Society and the Twin Cities Urological Society.

His wife, Flossie, survives him.

FRANK G. HEDENSTROM, M.D.

Dr. Frank G. Hedenstrom, 79, St. Paul pediatrician for more than 50 years, died November 3. A Graduate of the University of Minnesota Medical School, Dr. Hedenstrom was a staff member of Bethesda and Children's Hospitals.

He was a member of the American Medical Association and the Ramsey County Medical Society and a 50 Club and Life Member of the Minnesota State Medical Association.

Dr. Hedenstrom is survived by his brother, E. Axel.

DAVID HOWARD ROLIG, M.D.

Dr. D. Howard Rolig, 63, St. Paul physician, died September 7. Born in St. Paul, Dr. Rolig attended the University of Minnesota Medical School.

He was a member of the American Medical Association, the Ramsey County Medical Society and the Minnesota State Medical Association.

He is survived by his wife, Grace, and daughters, Mrs. Sam Olsen, Mrs. Bruce Ivascu, Mrs. Lynn Mortensen and Nancy.

CLARENCE A. STRUNK, M.D.

Dr. Clarence A. Strunk, 74, Minneapolis physician, died September 5. Educated at the University of Minnesota Medical School, Dr. Strunk was a former staff member of St. Andrew's Hospital, Maternity Hospital and Glen Lake Sanatorium.

He was a member of the American Medical Association, the Hennepin County Medical Society and the Minnesota State Medical Association.

Dr. Strunk is survived by his wife, Gertrude.

JOHN JACOB KAPLAN, M.D.

Dr. John Jacob Kaplan, 61, Minneapolis internist, died August 19. A University of Minnesota Medical School graduate, Dr. Kaplan interned at the Hennepin County General Hospital.

He was a member of the American Medical Association, the Minnesota State Medical Association and the Hennepin County Medical Society. He was also a fellow in surgery at the Mayo Clinic.

RAY R. KNIGHT, M.D.

Dr. Ray Roberts Knight, 92, Minneapolis specialist in gastroenterology, died September 14. He was born in Nokomis, Illinois, educated at the University of Minnesota School of Medicine, and interned at Asbury Hospital.

He was a former professor of oral diagnosis, University of Minnesota, a member of the American Roentgen Ray Society, the Radiological Society of North America, the American Medical Association and the Hennepin County Medical Society. Dr. Knight was also a Life and 50 Club Member of the Minnesota State Medical Association.

Mike Finamore was told he had leukemia. Nine years ago.

When Mike Finamore was thirteen years old, he was told he had leukemia.

At that time, this meant he had five, maybe six months, to live.

But just about then, leukemia research produced some dramatic results:

A special combination of drugs that would kill the leukemia cells in the blood and permit the person to live longer than ever before.

So Mike was treated. And it worked.

He didn't die.

Instead, he became one of the fortunate few to have leukemia and live. And today his weekly treatments enable him to lead a normal life.

In fact, right now he's putting the roof on a house he built himself.

And when it's finished there will be a double celebration.

The new house. And Mike's 22nd birthday.

Most people expect presents. Mike's happy just to have a birthday.

We want to wipe out cancer in your lifetime. Give to the American Cancer Society.

Will be responsible for O.S.H.A. compliance and will supervise all medical exams. Wouldn't you like the luxury of regular 8-5 hours? Call C. Feste collect at 612-544-8601. Employment Counselors.

This hilarity, this way of talking and drinking, which seemed to me in the others the mere results of bad company or bad habits, seemed in Marguerite a necessity of forgetting, a fever, a nervous irritability. At every glass of champagne her cheeks would flush with a feverish colour, and a cough, hardly perceptible at the beginning of supper, became at last so violent that she was obliged to lean her head on the back of her chair and hold her chest in her hands every time she coughed.

I suffered at the thought of the injury to so frail a constitution which must come from daily excesses like this. At length, something which I had feared and foreseen happened. Toward the end of the supper Marguerite was seized by a more violent fit of coughing than any she had had while I was there. It seemed as if her chest were being torn in two. The poor girl turned crimson, closed her eyes under the pain, and put her napkin to her lips. It was stained with a drop of blood.*

*Alexandre Dumas fils: *The Lady of the Camelias*, 1848, Chapter 9.

Quote: The AMA doesn't represent me Unquote.

Maybe that's the way you feel. Thinking we do little to protect your way of life. Or that we don't share your views.

If it be true . . .

Who did successfully testify against a headlong rush into a large-scale HMO program?

Who did propose a program of *voluntary* national health insurance and succeeded in enlisting more Congressional co-sponsors for it than any

other national health insurance bill?

Who did propose the development of nationwide community emergency medical services? Who did promote maternal and child care programs? Federal aid to medical schools? Stronger occupational health and safety laws?

The AMA. The fact is, the AMA works hard—and effectively—to represent your interests.

Obviously, we can't represent the views of all physicians all of the time. But the goals we do share far outweigh any differences that may separate us.

Join us.

We can do much more together.

American Medical Association
535 N. Dearborn St./Chicago, Ill. 60610

Book Reviews

DR. THOMPSON'S NEW WAY FOR YOU TO CURE YOUR ACHING BACK—Jess Stearn. Doubleday & Company. \$7.95.

The book is written by a layman, Jess Stearn, based on his own experience under treatment for a back condition by Dr. Thompson as well as other anecdotal material which he obtained from a variety of sources. The book is written for laymen. Most of the supportive material for the exercise treatment advocated is anecdotal in nature rather than scientific. Theoretical basis for the presumed satisfactory results leave much to be desired from a scientific standpoint and would be difficult for a physician and scientist to accept. The author suggests that exercises and changes in the spine can improve a number of conditions, including sinusitis. The exercises themselves seem reasonable for a person without serious spinal disease probably with no danger. The primary exercise which is presumed to cure "displacement of the sacro-iliac joints" is a rather simple one.

In general, my appraisal of the book is that it greatly oversimplifies complex back problems and offers a very simplistic therapeutic approach to back disorders. It also implies that treatment of the back can cure a number of non-skeletal, non-back related conditions which from a scientific standpoint are very difficult to accept.

Alvin L. Schultz, M.D.
Hennepin County General Hospital

HERITABLE DISORDERS OF CONNECTIVE TISSUE, Victor A. McKusick, M.D., 4th Edition, 878 pages, with 1099 illustrations and 2 color plates, The C. V. Mosby Company, \$32.50.

This book represents an exhaustive and meticulous study. It lists more than 114 pages of references. The book has chapters on such heritable disorders as the Marfan syndrome, Homocystinuria, the Weill-Marchesani syndrome, the Ehlers-Danlos syndrome, Cutis laxa, Osteogenesis imperfecta, Alkaptonuria, Pseudoxanthoma elasticum, the mucopolysaccharidoses and a chapter on genetic disorders of the osseous skeleton. The author makes a fine point that 'heritable disorders of connective tissue are not congenital malformations in the conventional sense.' He includes a comprehensive synopsis on page 860 of the more common heritable disorders. The book is addressed primarily to the family physician, the internist and the pediatrician. But it is also a useful reference for the other disciplines. The plastic surgeon may wish to refer to the chapter on Cutis laxa, and the cardiac surgeon to the Marfan syndrome. The rheuma-

tologist may look for new insights as to cause of degenerative connective tissue disease. Hopefully knowledge of the physiochemical details of the collagen molecule may soon match that of hemoglobin molecule. This book is recommended as a reference for clinical practice, investigation and research.

S. F. Ceplecha, M.D.
Redwood Falls, Minnesota

IS MY BABY ALL RIGHT?—Virginia Apgar, M.D., M.P.H. and Joan Beck, 1972, Trident Press, New York 492 pp., \$9.95.

When she was professor of anesthesiology at New York's Columbia-Presbyterian Medical Center, Dr. Virginia Apgar devised her system of scoring the newborn infant. Currently the apgar score is used almost universally throughout the world in delivery rooms. Dr. Apgar is now with the National Foundation, March of Dimes, where she directs the medical program on birth defects.

Joan Beck is a journalist and child-care columnist who collaborated with Dr. Apgar and produced this excellent volume on birth defects.

The first portion of the book describes basic reproductive biology, early embryology, pregnancy and delivery. Then follows a short discussion of general chromosomal defects and obstetrical complications.

The next 300 pages are comprised of 25 chapters each devoted to discussion of a common birth defect, e.g. cleft lip, cystic fibrosis, cerebral palsy, etc.

The last two chapters give practical suggestions to parents on ways to try to prevent birth defects and how to get genetic counseling.

The style is clear and direct with case histories woven into the discussions to heighten reader interest. Lay terms are used as much as possible, but the text is sufficiently technical so that much of the general population would have some trouble understanding portions of this book.

The promotional material on the dust jacket touts this as a volume for all prospective parents. I can think of many other books better suited to that purpose. I would recommend this book for parents of children with birth defects, people with family histories of genetic defects, and professionals such as nurses and therapists who work with these patients. I also recommend it for physicians who want an easy reading less technical review of birth defects.

of Librium
must a tranquilizer be
for severe anxiety?

As strong as Librium® 25 mg (chlordiazepoxide HCl)

The achievement of desired therapeutic results is often a function of the dosage strength as well as the drug's intrinsic action. Thus, when anxiety is *severe*, the 25-mg strength of Librium frequently provides the necessary antianxiety action with a minimum of unwanted adverse reactions. Librium 25 mg is a convenient dosage form for the relief of severe, incapacitating anxiety, specifically formulated to supplement your counsel and reassurance.

Benefits-to-risks ratio permits higher dosage

For over 13 years, Librium has been recognized for its excellent benefits-to-risks ratio, an asset in the *higher* dosage ranges as in more common clinical applications. Thus, the frequency of dosage with Librium 25 mg can be flexibly adjusted to the needs and response of the individual patient, up to 100 mg daily if required. Total daily dosage for the elderly and debilitated should not exceed 20 mg. When severe anxiety has been reduced, Librium dosage should be correspondingly reduced or discontinued entirely.

basic support
in severe anxiety
Librium® 25 mg
(chlordiazepoxide HCl)
1 capsule t.i.d./q.i.d.

Roche Laboratories
Division of Hoffmann-La Roche Inc
Nutley, N.J. 07110

Before prescribing, please consult complete product information, a summary of which follows:

Indications: Relief of anxiety and tension occurring alone or accompanying various disorders.

Contraindications: Patients with known hypersensitivity to the drug.

Warnings: Caution patients about possible combined effects with alcohol and other CNS depressants. As with all CNS-acting drugs, caution patients against hazardous occupations requiring complete mental alertness (e.g., operating machinery, driving). Though physical and psychological dependence have rarely been reported on recommended doses, use caution in administering to addiction-prone individuals or those who might increase dosage; withdrawal symptoms (including convulsions), following discontinuation of the drug and similar to those seen with barbiturates have been reported. Use of any drug in pregnancy, lactation, or in women of childbearing age requires that its potential benefits be weighed against its possible hazards.

Precautions: In the elderly and debilitated and in children over six, limit to smallest effective dosage (initially 10 mg or less per day) to preclude ataxia or oversedation, increasing gradually as needed and tolerated. Not recommended in children under six. Though generally not recommended, if combination therapy with other psychotropics seems indicated, carefully consider individual pharmacologic effects, particularly use of potentiating drugs such as MAO inhibitors and phenothiazines. Observe usual precautions in presence of impaired renal or hepatic function. Paradoxical reactions (e.g., excitement, stimulation and acute rage) have been reported in psychiatric patients and hyperactive aggressive children. Employ usual precautions in treatment of anxious states with evidence of impending depression; suicidal tendencies may be present and protective measures necessary. Variable effects on blood coagulation have been reported very rarely in patients receiving the drug and oral anticoagulants; causal relationship has not been established clinically.

Adverse Reactions: Drowsiness, ataxia, confusion may occur, especially in the elderly and debilitated. These are reversible in most instances by proper dosage adjustment, but are also occasionally observed at the lower dosage ranges. In a few instances syncope has been reported. Also countered are isolated instances of skin eruptions, edema, minor menstrual irregularities, nausea and constipation, extrapyramidal symptoms, increased and decreased libido—all infrequent and generally controlled with dosage reduction; changes in ECG patterns (low-voltage fast activity) may appear during and after treatment; blood dyscrasias (including agranulocytosis), jaundice and hepatic dysfunction have been reported occasionally, requiring periodic blood counts and liver function tests advisable during protracted therapy.

Supplied: Librium® Capsules containing 5 mg, 10 mg or 25 mg chlordiazepoxide HCl. Libritabs® Tablets containing 5 mg, 10 mg or 25 mg chlordiazepoxide.

Legacies of Regional Medical Programs

WINSTON R. MILLER, M.D.*

AS NEW LEGISLATION is being drafted to replace or revise Regional Medical Programs (RMP), legacies of this eight-year program would help to stimulate continuation of innovative features which have proved to be productive.

The movement for creative change in the health care system is like a great river which derives greatness from its many tributaries. In spite of local and national vicissitudes, this federal-private partnership program has provided tributaries to the river of change. Waters have cleared and become more sparkling, and there is an aura of cooperative enthusiasm. Professional satisfaction has been derived from central coordination and reporting, successful completion of innovative projects and adoption of demonstrated improvements by permanent components of the health care system.

Many private foundations and public institutions have recently adopted RMP objectives of regional cooperative arrangements, medical center outreach, bridging the gaps between new knowledge and its application, more optimum quality and equality of health care services, greater access to care, greater teamwork in delivery of services, and more relevant educational programs for health manpower.

Reports of RMP program activities provide the most readily understood evidence of accomplishments. But the unique characteristics of the RMP process, referred to by some as an *exquisite process*, constitute a principal virtue of the program. To the extent that innovative characteristics have been successful and productive, they can and should be incorporated into new or revised programs. This report presents a brief discussion of the principal components of the RMP process.

The FEDERAL—PRIVATE PARTNERSHIP concept implied a fraternal relationship between the fed-

eral bureaucracy and private health care units. Although difficult to accomplish and fraught with suspicions on both sides, this type of relationship needs further expansion as the federal financing role increases in the health care system. Regulation, licensure and certification alone cannot stimulate private initiative for optimum personal health care.

As a FREE-STANDING LOCALLY CONTROLLED HEALTH AGENCY, RMP was a first among federally supported programs. A separate corporate structure became favored, and the free-standing organization was timely and effective in bringing many dissident groups together during this period. Lack of political or institutional control at both local and national levels constituted both a virtue and a handicap. Lack of control by any existing organization allowed local authority with democratic decision making, but weakened support for continuation. Self-definition of "health service area" geographic boundaries supported functional arrangements but caused confusion and conflict in relationships to local governmental units. In spite of functional variations, state boundaries and some type of on-going organizational political attachment seem to offer more potential for the future.

The INCENTIVE AWARD SYSTEM to stimulate voluntary commitment of local resources and initiative represents a time-honored approach in American society. In RMP it was unique in reaching out to the "grass roots" and involving all of the "actors" in the health care delivery system. Also unique were the degrees of accountability, cooperation and evaluation required. Partly because of these features, all RMPs gained momentum slowly at first, and some never have achieved recognized success. Among the majority which have been successful, the incentive system has stimulated a progressive movement for improving the delivery of more optimum health care services. As cost controls become more ominous and authoritative, incentive programs like RMP be-

*Program Director of Northlands Regional Medical Program, Inc., from November 1967 to July 1973. Opinions presented are those of the author and do not constitute endorsement by NRMP, Inc., or the Department of Health, Education and Welfare.

come relatively more important for maintaining a desirable balance between regulation and private initiative.

The REGIONAL ADVISORY GROUP of each RMP implemented an unbiased decision-making process by a widely representative local council. As a sense of broad social responsibility was acquired, these groups demonstrated judicious concern in deciding the most important program activities to be supported with public funds. Many planning, review and management processes developed by RMP Regional Advisory Groups have been adopted by other organizations and agencies. The RAG deserves a better understood and more prestigious name, and a permanent role in Research and Development programs in health care.

RESEARCH AND DEVELOPMENT PROGRAMS like RMP have accelerated the advancement of Applied Research as a scientific discipline. Applied Research and Development can bridge the gap between acquisition of new knowledge by fundamental research personnel and wide application for social benefit by health service personnel. Characterization of unmet needs, measurable objectives in behavioral terms, milestones in project performance and objective evaluation of results constitute important components. Characteristics of Applied Research are demonstrated in many of the articles in this supplement.

The "GRAND PLAN" concept promulgated by RMP and other programs visualized a total picture of a completely coordinated plan. Rapidly changing key issues at relatively short intervals confuses a master plan approach, but many RMPs were able to have a *general picture plan* with several identified sections and pieces within these sections, which fit together like a jig-saw puzzle. For example, Quality of Care is one section and contains many components. In the series of reports in this publication, six articles relate directly to quality of care. It can be readily surmised how they fit together and provide mutual reinforcement. The Grand Plan concept stimulated each RMP to coordinate all activities closely and to direct more specifically what kind of projects would be funded. The "Contract Offering" approach pioneered by NRMP proved to be a successful method and was adopted by many other RMPs. It is a form of *directed* or *programmed* Research and Development. It is an interesting line of reasoning to pursue—we know what the general problem areas are; we know or can deter-

mine the various characteristics of a general problem in different areas; and with carefully planned support and guidance we can stimulate capable people to try out various plausible solutions to the specifically defined problem. If adequate evaluation is included, we can then demonstrate the degree to which the problem can be solved.

The MULTIDISCIPLINE STAFFS of RMPs consisting of highly qualified and respected professionals were unique and played key roles in catalyzing creative change. The *convening* role promoted cooperative commitment by many organizations to program objectives and maintained coordination of multiple interrelated activities. The *consultation* role provided assistance and guidance for many small institutions and for project planning, design and operation. The *liaison* role strengthened relationships between multiple segments of the health care system. *Planning and Feasibility Study* roles provided clearer definition of problem areas and guidance for development of plausible solutions. *Project Planning, Review and Management* roles carried out principles established by the Regional Advisory Group. *Communication and Public Relations* roles promote maximum application of RMP Research and Development activities. The traditional *administrative* role constituted only a small portion of staff responsibilities but did require finesse to establish and maintain a strong public image for the RMP. A "Directed Research and Development Program" needs this kind of a staff, and the RMP experience can serve as a prototype for future programs.

COORDINATED COMMUNICATION AND PUBLIC RELATIONS aspects of RMP demonstrated applications of those scientific disciplines to the health care system. The 65 extramural projects and 37 staff studies of NRMP resulted in 47 articles in health-related journals, over 13,000 column inches in newsprint in papers throughout Minnesota, an uncounted number of radio and TV programs, many conferences and symposia, and a set of "Archives of NRMP" containing 115 reports. All emphasized the coordinated regional program.

The large number of new processes pioneered by RMP for initiating and directing social change in the health care system readily explain why it was difficult for many people to understand what RMP was all about. And yet many of these new processes proved to be successful and will serve as prototypes for new programs. They constitute the greatest legacies of Regional Medical Programs.

Cervical Cancer Mortality Study

A Preliminary Report

CERVICAL CANCER MORTALITY SUB-COMMITTEE*

THE ORGANIZATION and objectives of the Cervical Cancer Mortality Study were described in the July 1972 issue of MINNESOTA MEDICINE. This study was undertaken by a sub-committee of the Obstetrics, Gynecology and Maternal Health Committee of the Minnesota State Medical Association and sponsored jointly by the Northlands Regional Medical Program, the Minnesota Division of the American Cancer Society and the Minnesota State Board of Health. It was designed to analyze retrospectively all deaths that occurred in a two-year period from cervical cancer in the state of Minnesota. By study of the circumstances associated with the course of the disease in each case, it was intended to delineate deficiencies in diagnosis, treatment, and followup care. The preliminary report encompasses the first 46 cases reviewed by the Cervical Cancer Mortality Sub-committee.

Materials and Methods

All death certificates listing carcinoma of the cervix or uterus as the cause of death for the calendar years 1971 and 1972 were extracted by the State Department of Health and sent to the investigator members of the sub-committee. These certificates were reviewed to determine the actual site of tumor origin. If a decision as to origin of the tumor could not be easily made, a detailed investigation was conducted and the collected data presented to the sub-committee for a decision. Most death certificates were, however, complete and accurate.

Cases were excluded from the study if primary treatment had been given out of state. To initiate a case study a questionnaire was mailed to the physician who signed the death certificate to ob-

tain the names of all other physicians including pathologists involved in the total care of the patient, as well as dates, place, and details of all hospitalizations. Once the questionnaire was returned all cytologic smears taken during the five years prior to diagnosis, and all cytologic and/or histologic material associated with follow-up care were requested. In addition, autopsy slides were requested where applicable. All cytologic and pathologic material was independently reviewed by a three member panel of pathologists to confirm the original diagnoses. Questionnaires were also sent to other physicians who participated in the patient's care, and in cases where radiotherapy had been administered the details of external beam and radium therapy obtained.

The pooled data for each case was organized to form a rough chronologic summary. In nearly every case, however, it was necessary for the case investigator to personally review hospital and office records, as well as interview one or more of the physicians involved to obtain complete details of the patient's history, diagnosis, therapy, and follow-up. The record reviews and personal interviews were conducted by physicians knowledgeable and experienced in the detection, diagnosis, and treatment of gynecologic malignant disease. Once the case summary was completed it was presented to the twelve member Cervical Cancer Mortality Sub-Committee for final review and evaluation.

In each case review several aspects of the cervical cancer death were considered by the sub-committee. The five year period prior to the onset of cancer symptoms was reviewed to ascertain the adequacy of gynecologic care, if any, received by the patient. The care in this period was considered adequate if a pelvic examination and a Pap smear were performed on an annual basis. If the five year period in question antedated the widespread use of cytologic screening, standards of adequate care were liberalized. In cases where

*This report was prepared by the Cervical Cancer Mortality Sub-committee of the Committee on Obstetrics, Gynecology and Maternal Health of the Minnesota State Medical Association. The project was a component of Northlands Regional Medical Program, Inc., supported by HEW grant #5 GO3 RM-00021. Opinions presented do not constitute endorsement by NRMP, Inc. or the Department of Health, Education and Welfare.

this antecedent care was considered inadequate, the committee judged whether or not the inadequate care contributed to the patient's death and assessed the responsibility to the patient alone, to the physician(s), or to both patient and physician(s).

The period from the onset of symptoms to establishment of the diagnosis of cancer was evaluated. Care was judged to be adequate or inadequate, and, if inadequate, contributory or non-contributory to the patient's death.

The procedures performed to establish a definite diagnosis of cervical cancer were reviewed. Procedures were classified as appropriate or inappropriate with respect to the clinical findings. For example, a cone biopsy of the cervix was considered inappropriate if a gross lesion was present. Appropriate procedures were classified as complete or incomplete and inappropriate procedures were ruled either contributory or non-contributory to the patient's death.

Consultation was not deemed necessary only if the responsible physician was a gynecologist or a radiotherapist. Consultation was judged as either appropriate or inappropriate. Inappropriate consultation was assumed to be inadequate whereas appropriate consultation could be either adequate or inadequate. Failure to stage the disease using FIGO guidelines, for example, was considered by the committee to be inadequate consultation even if the consulting physician was an appropriate consultant.

Primary therapy was assessed and considered either appropriate or inappropriate depending on the stage of the disease. The adequacy of therapy was also assessed. Follow-up care after primary therapy was considered by the committee using the criteria of a pelvic examination and Pap smear every 3-6 months for three years, then annually thereafter. Responsibility for inadequate care was duly placed.

Secondary therapy, if any, was considered as either palliative or curative. Evaluation of the adequacy of curative therapy was carried out.

Finally, the overall responsibility for non-cure was assessed. If, in the evaluation, death was determined to be the result of a disease other than cervical cancer, it was ruled non-preventable. This category also applied to deaths resulting from tumor progression in spite of appropriate therapy and to deaths from complications of that therapy. Only deaths resulting from progression

of the cancer following inadequate care and/or inappropriate treatment were considered preventable. In these cases, responsibility for non-cure was attributed to the patient alone, or physician(s) or to both the patient and physician(s).

Results

Of the first 46 patients whose cases were reviewed only six (13%) had adequate gynecologic care in the five years prior to symptoms. Of the 40 patients receiving inadequate care, over half had not consulted a physician over this period. Although the others had, for the most part, been under medical care regularly for unrelated medical and/or surgical conditions, a pelvic examination was not performed at any time. In all but three cases this inadequate care was deemed contributory to the patient's ultimate demise.

Once symptoms appeared 60% received adequate care and a prompt tissue diagnosis was established; 40% received inadequate care. In these the majority did not seek medical attention within a reasonable period of time. In a few cases, the failure of the physician to aggressively seek the cause of the abnormal symptoms resulted in undue delay in establishing a diagnosis.

Example: Case #6 "A 69-year-old lady complained of post-menopausal bleeding. Pelvic examination by her physician found the vaginal apex to bleed easily. A Pap smear was negative. A diagnosis of atrophic vaginitis was made. Nineteen months later when heavy vaginal bleeding occurred, a Stage II-A carcinoma of the cervix was discovered."

Only 63% of the patients received appropriate and complete diagnostic studies. Twenty-two percent had an obvious cervical lesion yet inappropriate steps were taken to establish a diagnosis. In some cases only a Pap smear was done and in others a full scale cervical conization was performed.

All patients received appropriate consultation prior to therapy. In 20%, however, consultation was inadequate because the consultants failed to stage the lesion. In one patient the consultant described a pelvic mass and obtained a Pap smear which was reported as Class IV. A tissue diagnosis, however, was never established.

Primary therapy was appropriate and adequate in 72% and for the most part consisted of irradiation therapy to the pelvis using one of several standard techniques. Some patients had inadequate radiation therapy because deterioration of their medical condition precluded further treatment.

ment. One patient had the radium applicator dislodge from the cervix at an unknown time during therapy; one patient's therapy was interrupted because of an exacerbation of pelvic inflammatory disease and additional dosage was not added to compensate for the significant delay. Two patients were treated with chemotherapy alone because of advanced disease and two received no treatment at all.

Follow-up care after primary therapy was accomplished in almost all patients. In most follow-up care was deemed adequate, and consisted of regular examinations and Pap smears. In those having inadequate care the inadequacies were generally attributable to failure of the physician to recognize signs or symptoms of recurrent or persistent disease. In only one case did the patient herself bear the full responsibility of inadequate follow-up care.

Example: Case #12. "A 61-year-old woman was treated with irradiation for a Stage I-B carcinoma of the cervix. She returned to her physician at regular intervals over the next several years. Eighteen months after therapy a suspicious Pap smear was obtained. A cervical biopsy showed only inflammation. Suspicious or positive Pap smears were obtained four, six, and seven years after treatment but no further investigation was done. Thirteen years after treatment a gross extensive recurrence of cancer was found by another physician."

Treatment for recurrent or persistent disease was carried out in the majority of patients, but an attempt at cure was carried out in only five. Four of these had radical surgery. Except for one post-operative death, the patients succumbed to recurrent disease, two of them living five additional years.

Discussion and Conclusion

The Cervical Cancer Mortality Study is now one year old and the review of the deaths for 1971 and 1972 is approximately one-third completed. To date, only gross patterns are discernable. In general, however, management of the patient with cervical carcinoma in Minnesota appears to be reasonably adequate once the patient reports to her physician. There are, unfortunately, inordinately large numbers of women who are not receiving an annual pelvic examination and Pap smear screening. In most cases, these are women who do not seek medical attention of any kind, and for various reasons may not be aware of the value of such screening. The most disillusioning aspect of the study, involves the significant numbers of women who, despite regular contact with their physician, do not receive a pelvic examination. It is reasonable to assume that if survival statistics for patients with carcinoma of the cervix are to be improved, earlier detection is an absolute necessity.

Problem Oriented Medical Records in A Private Hospital

DONALD S. ASP, M.D.* and JO M. BRASHEAR, R.N., B.S.†

SINCE PUBLICATION of Weed's, *Medical Records, Medical Education, and Patient Care*,¹ there has been increasing enthusiasm for Problem Oriented Medical Records (P.O.M.R.) throughout the country. Justification for the

*Project Director of this study, is in the Department of Family Practice, University of Minnesota.

†Nursing Coordinator and Health Record Analyst at Bethesda Hospital.

This project was sponsored by Bethesda Lutheran Medical Center. It was a component of Northlands Regional Medical Program, Inc., supported by HEW grant #5 GO3 RM-00021. Opinions presented do not constitute endorsement by NRMP, Inc. or the Department of Health, Education and Welfare.

Problem Oriented System as a tool for improved patient care and problem solving is best illustrated in the article by J. Willis Hurst, M.D., entitled "Ten Reasons Why Lawrence Weed is Right."

Drawing from Weed and Hurst and our own practical experience it is the purpose of this paper to describe a project which was developed to accomplish a threefold mission:

1. Adoption of P.O.M.R. in a community hospital.

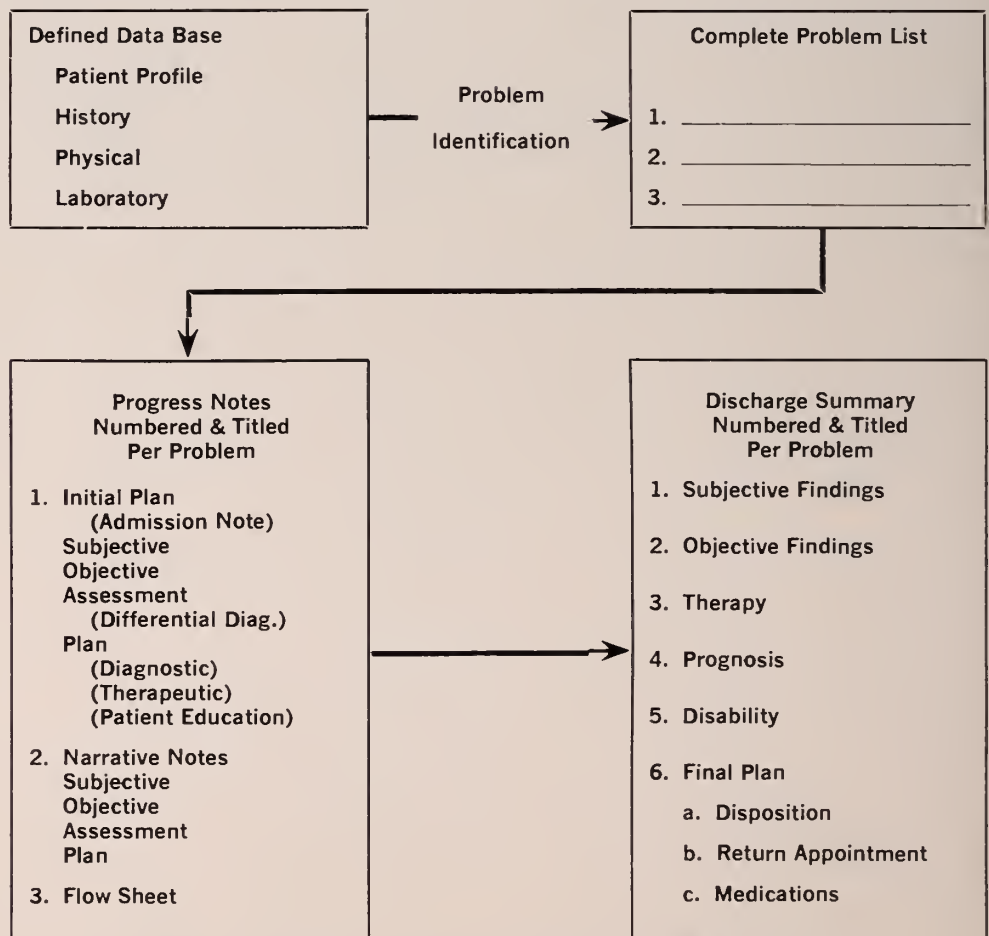

Figure. Components of the Problem Oriented Medical Record

2. Application of medical audit to P.O.M.R.
3. Development of team care approach through use of interdisciplinary health records.

To many physicians medical records (including hospital charts, insurance and medicare forms and office records) are not among the most enjoyable features of the practice of medicine. Fortunately the problem oriented system has made a dramatic change in the attitudes of physicians and nurses toward medical records. At our institution a number of staff physicians and nurses were very interested in the problem oriented approach to medical care. In fact it was their enthusiasm that precipitated the undertaking of this project.

Summary of the Problem Oriented System

The problem oriented medical record consists of four components: data base, problem list, progress notes with initial plan and discharge summary (Figure).

An essential part of the data base is the patient's profile. To quote Dr. Weed, the patient's profile is "the physician's understanding of the whole patient in his life situation."¹ The patient profile should provide anyone viewing or reviewing the chart some understanding of the patient's typical day, his life style, his occupation and hobbies, his relationship to friends and family, and his general attitude toward his health and problems. It replaces the traditional "social history" in a much more structured fashion. The remainder of the data base consists of a traditional history and physical including a chief complaint and baseline laboratory information.

The problem list, key to the P.O.M.R. should list "problems" at the level of understanding of the physician at the time he compiles the list. Although a problem list generally will grow as more problems are elucidated, the basic problem list can usually be completed within 24 hours. Problems can be defined as "anything that concerns the patient or the physician"¹ and should include the complaint leading to admission, significant items in the past medical history, significant abnormal laboratory values, and important behavioral or psycho-social problems.

Progress notes should be recorded in a systematic fashion clearly demonstrating thought processes of the physician or nurse as well as basic medical information. The initial plan should include systematic evaluation of each problem at

the level of sophistication available at the time. It also includes diagnostic procedures contemplated, therapeutic plans, and appropriate patient education. Progress notes are organized by problem number, problem title and the date and time of writing. A useful new format is the S.O.A.P. technique:

S. Subjective information documents complaints or concerns of the patient relative to the particular problem.

O. Objective information includes physical findings and laboratory data regarding the problem.

A. Assessment reflects the physician's or nurse's interpretation of physiologic or psychologic implications of subjective and objective findings. Inasmuch as the problem list reflects information available at a particular time, assessment may include diagnostic guesses and "ruleouts" as well as more obvious and substantiated conclusions.

P. Plan demonstrate physician or nurse objectives in alleviating, correcting or modifying the problem.

In an attempt to condense and improve medical records, flow sheets are becoming more important as a means of graphically demonstrating pertinent information in a sequential and easily understandable fashion.

As the final component of the problem oriented record, the discharge summary includes separate notations for each problem. It consists of both subjective and objective information, including results of laboratory procedures and therapeutic measures for each problem during the hospital stay. In addition it includes: condition on discharge, prognosis, duration of disability, a final plan for disposition of the patient, return appointments, and all discharge medications. The summary is designed to provide for continuity of care from hospital to clinic, extended care facility or nursing home and must therefore be completed at the time of discharge. As a secondary benefit it provides office staff with information necessary to complete insurance, compensation, medicare, or welfare reports.

Methodology

Initiation of change in traditional systems is a difficult process. This is particularly true in the area of medical records since effects on the patient are not as dramatic as those of a new surgical procedure or a new medication. As Dr. Weed

has said, "when you decide to change the basic premises under which you have been operating—memory dependency, uncoordinated specialization, no feed back, no controls—when you decide to change those, of course it's going to be hard."³

Initially we developed a concise but reasonably complete manual for use of the problem oriented record system. Copies of this manual were distributed to all nursing stations, to all resident physicians and to interested staff physicians. The manual has proven to be the most significant product of this project. It provides the reader with a good understanding of the problem oriented system without extensive reading.⁴

A group of interested staff physicians and family practice residents initiated problem oriented records on approximately half of the admissions to the hospital. As more physicians were exposed to the problem oriented records of their colleagues, requests were received from additional physicians for an opportunity to become involved in this method of record keeping.

At the same time nurses and paramedical personnel began problem oriented techniques. The nurse medical record analyst instructed staff nurses, both in groups and on a one-to-one basis in problem orientation of nursing notes. This process was started on a single station and gradually expanded to include all nursing stations. The records analyst was available at any time for consultation in problem identification and charting clarification. Didactic sessions were held with nurses on evening and night shifts as well. As nurses became more comfortable with problem orientation of their records and in particular with the concept of making broad assessment of subjective and objective findings, the concept of interdisciplinary charting gained increasing acceptance. The development and merits of this method will be published in a separate report.

Audit

To paraphrase Dr. Weed, if one intends to approach medical records in a scientific manner, it is essential:

1. That you have a system,
2. That you audit performance,
3. That you audit the system itself.

At Bethesda Hospital three types of audit were performed. First was an audit of the medical record itself; second was a, subjective audit of physicians and nurses regarding attitudes and

opinions of the record; and third was an audit of the quality of care delivered for specific diseases comparing problem oriented and traditional records.

Chart Audit

A. Non-Problem Oriented Records

All audits were performed by physician using a specially prepared audit form. (Sample shown on page 16). Of the 29 non problem oriented charts reviewed, two were found to be excellent, eleven acceptable and sixteen unacceptable. Significant comments by auditors were as follows: All problems not evaluated and followed; admission not justified; complications not documented; no justification for most orders main problem was incomplete evaluation no documentation of many problems recognized on review.

B. Problem Oriented Records

Problem oriented records were reviewed on three occasions. A sample of the audit form is shown on page 17. Initial audit of problem oriented records during the developmental stages of the project involved sixty charts. The results of the review were as follows: Excellent—1, good—25, acceptable—3, improvement needed—26, unacceptable—5. Significant findings of reviewers are broken down into various components of the record system. The patient profile was not adequate in almost fifty percent of cases. Problem lists in many instances were incomplete; many inactive problems were not mentioned; and many problems were not kept current. Analysis of progress notes indicated that the S.O.A.P. format was frequently not used and there seemed to be problems with communications. Twenty-two percent of the charts had no initial plan. The principal deficiency in the discharge summary was that all listed problems were not discussed. Evaluation of nurse notes revealed difficulties with format, lack of objective data one-third of the time, a total lack of impressions and obviously poor communications with physicians.

The audit of 51 charts during the intermediate phase of the project showed little difference in the overall evaluation: One rated as excellent, twenty-two as good.

twenty needing improvement, seven as unacceptable and one as poor. The findings of reviewers were essentially the same as those in the previous audit.

The final audit, involving 25 interdisciplinary charts showed definite improvement: Sixty percent received an excellent or good rating; thirty-two percent showed need for improvement; and eight percent were considered unacceptable. Reviewers commented that nurses' notes had improved and more nursing impressions were recorded on progress notes. In addition, they found that both communication and the quality of nursing observations were markedly improved. The principal deficiency with the charts continued to be that of keeping the problem list current and complete with inclusion of inactive problems.

Subjective Audit of Problem Oriented Record

A subjective audit questionnaire was distributed to 20 physicians and 43 nurses in October 1972 and February 1973. Responses in October included 14 physicians and 32 nurses; in February 14 physicians and 36 nurses. Results were as follows:

1. Has P.O.M.R. changed your approach to the patient?

	M.D.		Nurses	
	October	February	October	February
Yes	50%	71%	18%	55%
No	35%	7%	81%	41%
Questionable	14%	0%
No Response	7%
Other*	14%	2%

*Always used P.O.M.R.

Comments: More complete evaluation; more organized, logical approach; more complete care of total patient, more interest in social aspects; more aware of problems other than admitting diagnosis; helped improve my observation skills; I ask questions now requiring subjective responses.

2. Do you believe your patient care has improved?

	M.D.		Nurses	
	October	February	October	February
Yes	79%	86%	38%	50%
No	7%	62%	47%
Questionable	14%	2%
Other*	14%

*Always used P.O.M.R.

Comments: Able to organize and keep track of specific and multiple problems; problems followed up which were otherwise ignored; more thorough; fewer overlooked lab values; reminder of patient's total condition; helps establish priorities in care; helps to quickly evaluate changes in patient's condition; better observations—more effort to obtain subjective viewpoint.

3. Do you feel the chart is more useful to you?

	M.D.		Nurses	
	October	February	October	February
Yes	93%	93%	97%	72%
No	7%	3%	23%
Questionable	7%
No Response	5%

Comments: Able to review chart faster and more effectively; easier to extract data and follow patient's condition; easier to read; organized and more systematic, more meaningful; more aware of doctor's thinking; better communication.

4. Has the P.O.M.R. improved communication between all involved in the care of your patient?

	M.D.		Nurses	
	October	February	October	February
Yes	72%	93%	75%	56%
No	14%	19%	30%
Questionable	7%	7%	6%	3%
No Response	11%
"Potentially"	7%

5. Has the P.O.M.R. assisted your prompt evaluation of hospital patients not under your direct care, but who require your immediate aid?

	M.D.	
	October	February
Yes	86%	93%
No	7%
Questionable	14%

6. Has the P.O.M.R. had any bearing on length of your patient's hospital stay?

	M.D.	
	October	February
Yes	7% ▼ Stay	14% ▼ Stay 7% ▲ Stay 14% No details
No	40%	43%
Questionable	43%	21%

Audit of Quality of Care

To audit the quality of care we used disease entities for which our hospital has established pattern criteria. This type of audit has been performed for over two years and is essentially the same as the quality assessment program of the Joint Commission on Accreditation of Hospitals. Comparative audits were conducted to study problem oriented records versus traditional records in urinary tract infection, hypertension and presurgical evaluation. With the number of patients involved and the limited time available we were not able to demonstrate any statistically significant difference in quality of care between the two record systems. A single exception was the presurgical evaluation study in which electrolyte abnormalities and liver function abnormalities were noted as problems on the problem list of P.O.M.R. records and acknowledgment of these abnormalities was made by the attending physician with appropriate therapy. In contrast, in the non-problem oriented records the instances of abnormal chemistries or electrolytes were not documented nor was there any documentation of an effort to modify these abnormalities prior to general anesthesia. It

is our intent to conduct more extensive audits of this nature, recognizing their limitations, but hopefully drawing some conclusions concerning relationships of quality of care to the quality of the record.

Summary

A workable and concise manual of the problem oriented record system proved to be very helpful in implementing P.O.M.R.

Family practice residents and interested staff physicians applied problem oriented charting to the majority of patients in a community hospital.

After nurses became proficient in the techniques of problem oriented nursing notes, integrated charting was implemented on a substantial portion of the patient population.

Audits of the quality of the medical record showed improvement as physicians and nurses became more familiar with this system. Attitude surveys of the P.O.M.R. demonstrated favorable reception and supported continuation of this program.

Additional audits are being conducted in an effort to measure more accurately the effects of the problem oriented system on quality of patient care.

The problem oriented medical record system has made a dramatic impact on medical records and medical education. However, it is primarily a tool for problem solving and does not lessen the need for good clinical judgment. It does serve as a vehicle for improving health maintenance requiring recognition of the patient as a whole, including psycho-social as well as pathophysiologic problems.

"If you say the whole patient is not your responsibility, you are a technician."⁵

Continuing Education for Nurses

A Problem Oriented System

LAURENCE A. SAVETT, M.D.* and VIVIAN GOOD, R.N.†

NURSES CAN PLAY a greater role in the care of hospitalized patients. The traditional view of nurses held by many other health care professionals has not included the nurse as a data collector and decision maker, even though the nurse has often functioned in those roles. Indeed, many physicians see the nurse as one who says "I am only following orders."

In order to improve patient care at United Hospitals, Miller Division, St. Paul, Minnesota, a program of continuing nurse education was begun in August 1972. The program tried to enlarge the data collection and decision-making role of the nurse, and to improve communication between physicians and nurses.

The educational program utilized the problem oriented system^{1,2} to educate nurses around individual patient care situations, taking maximum advantage of the "teachable moment." The term "teachable moment" is one used to describe the following concept: In the clinical situation the best setting in which to learn new information is one at or near the bedside, when the need for, and application of, the new information is immediate.

The fundamental purpose of most hospital admissions is to make decisions and solve problems for the patient, when such tasks cannot be done as an out-patient. The nurse often functions in a decision-making role. Although the physician decides the diagnosis and prescribes treatment, the bedside nurse is often called upon to make important moment-to-moment decisions—

Is the patient's headache a tension headache (which requires only aspirin), or a symptom of a hypoglycemic reaction or of a subarachnoid hemorrhage (each of which requires immediate intervention by a nurse or physician)?

Is the patient confused because he is senile

(which requires reassurance and a night light), or because he is sedated too much (which requires change in drug therapy), or because he is hypoxic (which requires major intervention)?

Many of the major decisions in patient care consequently involve interim solutions to diagnostic or therapeutic problems. What is the cause of the patient's headache? What is the cause of the patient's confusion?

Before we began this project, it was not uncommon to find that staff nurses did not know why the patient was admitted to the hospital, whether any new problems had developed since admission, or why they were giving a certain medication or treatment. Many therapeutic maneuvers were carried out without any notation of results. The chart of a patient given nitroglycerin as a diagnostic test for angina, for example, had no notation anywhere in the nurse's notes about the effect of the medication. Many observations were made without an assessment of their meaning. A nurse would duly record in her progress notes that a patient experienced lightheadedness, diaphoresis, extreme hunger and confusion, but she would not conclude that the patient was having a hypoglycemic reaction from the regular insulin administered three hours previously. Many such deficiencies in nursing observations and judgments diminished the effectiveness of patient care.

Just as often, however, the nurse provided excellent patient care—making appropriate observations, giving treatment judiciously, providing emotional support, and teaching the patient about his illness. But such activities were rarely recorded and rarely was this superior nursing care commended and given special recognition. A professional should know when she is doing a good job, receive reinforcement by superiors, and help in teaching her peers.

The self-image of nurses was identified as an additional problem. Often the nurse was reluctant to suggest modes of care, question orders or bring new information to the attention of the physician, and this reluctance reflected her own self-view as that of a lesser professional. The realities of the

This project was sponsored by United Hospitals, Miller Division, St. Paul, Minnesota. It was a component of Northlands Regional Medical Program, Inc., supported by HEW grant #53-O3 RM-00021. Opinions presented do not constitute endorsement by NRMP, Inc., or the Department of Health, Education and Welfare.

hospital situation are, however, that the bedside nurse is in attendance around the clock and is often a more appropriate person to make interim decisions and judgments than the attending physician who may be a floor, a block, or a mile away.

Objectives

Traditionally the "nursing process" has been subdivided into four parts: assessment, planning nursing care, intervention, and evaluation of care.³ The objective of this project was to more fully develop three roles of the nurse which express the "nursing process" somewhat differently—the nurse as data collector, the nurse as decision-maker, and the nurse as patient-teacher.

Methods

Four nursing stations (three general medical-surgical units and one intensive care unit) were selected to implement the program.

Nurses on each station were instructed in the problem oriented system of collecting and recording data. The following points were stressed:

1. The nurse should be able to identify all of the patient's problems, and a list of problems should be included in the patient's kardex. Communication from nurse to nurse and from shift to shift should

center on describing the progress of each of the defined problems. In a situation where there was no physician-generated problem list, the nurse was instructed to generate such a list—from her own interview of the patient, from the physician's history and physical, from data evolving during the course of hospitalization, or preferably, from combinations of these three sources.

2. The nurse should identify new problems as they evolve and assess their significance. Two critical questions should be asked: "Is the new problem related to any of the old problems?", and "Is the new problem related to the treatment of any of the old problems?"
3. Data should be recorded in the nurse's notes according to the problem to which they relate. A structured method of recording makes data reproducible and provides quick access to important information for nurse colleagues. The S.O.A.P. method of recording (Figure 1) was selected as best suited to the purpose of the project.
4. The problem list could not be considered complete unless all drugs and treatments could be related to identified problems.

Each nursing station was oriented to the system on one day and the method was implemented immediately on the following day. Since the project centered around individual patients, teaching was directly applied to patients at hand. No purely didactic sessions were held.

At least once a week, one of us observed a nurse report session at which the day shift nurses reported on patient progress to the evening shift.

	Problem	Progress Note
3/7/73 8 A.M.	#1—Uncontrolled Diabetes Mellitus a) Insulin Administration	S: "I have always administered my own insulin and am not aware of any problem. I always inject insulin into my thighs." O: Observed patient draw up and administer insulin herself. She did not cleanse bottle with alcohol prior to drawing up insulin. Drew up 15 U NPH instead of prescribed 18 U and then expelled approximately 4 U when trying to eliminate air bubble. Injected into indurated area of right thigh. A. Lacks understanding of proper technique and importance of accuracy. Inaccuracy of insulin dose compounded by visual problems. Induration of thighs due to lack of rotation of injection sites. I feel difficulty with diabetes control related to above findings.
3/7/73 1 P.M.	#1—Uncontrolled Diabetes Mellitus a) Insulin Administration	P. Reviewed correct technique for insulin preparation and administration with return demonstration using syringe with wide calibrations. Instructed re: rotation sites and suggested use of abdomen. Reported visual problems to physician for follow-up. A. New syringe effective in facilitating accuracy of dosage. Technique understood and appropriately executed.

L. Rheault, R.N.

Key: S—subjective data (patient perceptions); O—objective data (observations by nurse or other health team members); A—assessment (nurse's conclusions about the meaning of the observations); P—plan and actual intervention, including teaching of patient.

Fig. 1—Problem oriented nurse's progress notes.

The observer reviewed patient charts before the session in order to be familiar with each patient's medical history and clinical course. The nurse responsible for the patient reported the following information to her relief: patient's name and clinical problems, observations during the shift pertinent to each problem, overall progress of that problem, and priorities of care for the next shift. Most patients had more than one problem on which to report.

The role of the project directors in these teaching sessions was two-fold:

1. To structure the nurse session according to the following format:

Are all of the patient's problems identified?

Are appropriate observations being made on this patient with diabetes (or coronary heart disease, or herniated disc, etc.)?

If they are not, what observations should be made?

What complications should one look for in this patient who has just had a cholecystectomy (or a myocardial infarct, or a pulmonary embolus, etc)?

Do all prescribed medications and treatment correspond with defined problems?

Are new problems related to any old problems, or to treatment of any old problems?

2. To act as information source, and raise the pertinent clinical questions about each patient's problems.

When a nurse notes "muscle spasms" in a patient who has just had a thyroidectomy and she does not recognize that she is observing hypocalcemic tetany, the teaching begins with this fact. The discussion then encompasses, in succession, causes of hypocalcemia after thyroidectomy, complications of thyroidectomy in general, other causes of hypocalcemia, and complications of treatment.

The following questions about a patient with diabetes mellitus are raised and discussed:

What are the reasonable goals for management of carbohydrate metabolism? Discussion includes rationale for therapy and use of insulin.

What complications may confuse urine test readings? Discussion includes the fact that a poorly emptying diabetic neurogenic bladder provides a urine specimen which inaccurately estimates the blood sugar.

Why does the diabetes go out of control? Discussion includes various events usually upsetting diabetic control—infection or other acute illness, diet abuse and poor injection technique.

Nurses were given homework in the form of clinical problems. Descriptions of clinical situations presented a need to recognize and interpret the meaning of a new problem. The homework as discussed at the next weekly meeting. Discussion of the case illustrated in Figure 2 touched on: (1) the need to recognize that the patient was confused; (2) possible causes of confusion, suggested by the list of problems and treatments—hypoglycemia, too much sedation, or worsening of congestive heart failure; and (3) the necessary nurse intervention for this situation.

Sylvia Glick, age 72, has been hospitalized one week. At 4 P.M. she calls the nurse and says repeatedly, "Five times five is twenty-five, five times five is twenty-five." Prior to that time, she had been perfectly lucid.

Problem	Treatment
1. Diabetes Mellitus— onset 1954	1500 Cal. diet NPH insulin 40 units q A.M.
2. Cerebral arteriosclerosis— onset 1968	Valium 5 mgm. tid
3. Coronary heart disease Congestive heart failure— onset 1962	Lanoxin 0.25 mgm. q.d.
What's the name of the new problem? How would you proceed to handle it?	

Fig. 2—Sample homework case study

During the week, one of us (V.G.) visited the nursing station, reviewed records, and moderated sessions with floor nurses. In these sessions each nurse reviewed a chart on a current patient cared for by one of her nurse colleagues. The following questions were raised:

Do the notes reflect recognition of the patient's problems, logical reasoning, and the care provided to the patient?

Was the data recorded sufficient to describe the problem and its course?

Was an appropriate assessment made of new observations?

What was good about the care given?

How would you improve upon the care given?

What is the progress of nurse education for this patient?

Results

Did this project and its approach to nurse education actually improve patient care?

The Nurse as a Data Collector and Decision Maker

Nurses identified more patient problems and acted upon them. A number of specific instances were observed where the expanded role of the nurse was important in improving care.

1. An elderly patient with anemia was admitted from a nursing home. Hemoglobin was 8 gm.%. The physician continued the prn order for Phenaphen for arthritis. Recognizing that Phenaphen contains aspirin, the nurse reasoned that aspirin could cause gastritis and occult bleeding. She called the attending physician and shared her reasoning with him. The physician discontinued this medication and ordered a bland diet, antacids and appropriate tests to identify the source of blood loss.
2. A middle-aged woman with varicose ulcers was placed at enforced bedrest by her physician. She had a history of phlebitis and pulmonary embolus following a cholecystectomy three months previously. The nurse recognized that enforced bed

rest placed this patient at greater risk for further leg vein thrombosis and pulmonary emboli, and she called the physician who then ordered anticoagulant therapy for prophylaxis.

3. A nurse began hot packs on a patient with an infiltrating I-V. She commented, "Why wait until the patient complains of pain and phlebitis develops?" She recognized that infiltrating I-V's place the patient at risk for phlebitis and initiated an appropriate preventive measure.
4. A middle-aged patient developed a fecal impaction. The nurse called the attending physician to suggest substituting an alternative to the prescribed codeine analgesic. She had correctly asked herself "Is this new problem, fecal impaction, related to current treatment?" By simply scanning the medication list she saw that the patient was taking codeine.
5. A patient with chronic obstructive lung disease developed moderately severe headaches while receiving aminophyllin. The nurse wondered if the headache was caused by the aminophyllin and raised this question with the physician. He lowered the dose of aminophyllin, and the headache disappeared.
6. A patient on warfarin developed a bladder infection with fever. Aspirin was ordered for the fever, and the nurse, recognizing that aspirin could potentiate the anticoagulant effect of warfarin, called the physician who substituted acetaminophen for the aspirin.

About fifty nurses participated in this project and responded to a questionnaire exploring its impact on their practice. Most felt that the problem oriented approach made them more aware of why patients were hospitalized, why tests were ordered, and why certain medications and treatments were prescribed. Most felt that they had become more skilled in identifying new problems and more thorough in seeking the cause of new problems.

The Nurse as Patient Teacher

The nurse's role as patient teacher became more visible. One nurse evolved an extremely effective way of evaluating a patient's management of diabetes. She observed the several steps involved as the patient removed insulin from the vial and gave the injection. Whenever a step was executed in a faulty way, she immediately gave instructions for the correct technique. Her method of recording (Fig. 1) was extremely useful to the physician in re-emphasizing a much-overlooked cause of failure to control diabetes—faulty self-administration of insulin.

Complicated instructions to the patient were no longer concentrated in the last day of the hospitalization. Instead the nurse often used much of the entire hospitalization to teach her patient and to reinforce her teaching with repetition. During this time she taught the diabetic patient about hypoglycemia and other aspects of diabetic care.

She counseled the patient on anticoagulants about the various manifestations of bleeding. She laid out a schedule of drug administration for the post-pancreatectomy patient who required twenty pills a day and used the hospitalization time to explain the rationale of therapy.

Nurse Satisfaction and Self Image

Did the nurse's satisfaction with her own work improve? Did her own self-image improve? Most participating nurses responded "yes" to these questions. Nurse morale on stations using this system improved. Nurses began to teach each other. They felt more comfortable in dealing with each one of their patients because they were aware of all of the patient's problems. The following comments illustrate: "If I don't know something, I feel compelled to look it up and study about it." "I feel as though I am treating a whole patient rather than just a disease." "I am finding myself more willing to find out things about patients, both physical and social." "I am finding I am more comfortable working with various diagnoses." "I feel more involved with the patient—there is more communication with doctors concerning daily progress and medication . . . and all this is a learning process." "It's good to see how my evaluations and notes have helped the patient's progress."

Nurses were less and less reluctant to question physicians about diagnostic concepts and rationale for therapy. As the nurse became more aware of the reasons for tests and therapy, she became better able to interpret hospital events to the patient.

Discussion

This was a project for improving care through ongoing day to day nurse education centered around the nurse's current patients. The problem oriented system was adopted to emphasize many of the steps involved in collecting data, making decisions and teaching patients. The problem oriented system does not guarantee good care, but it does provide a structure and an auditable record so that one can identify care which needs to be improved.

The problem oriented system allows one to identify different levels of nurse performance, and the needs at each level. The skilled nurse does not necessarily improve with the system, but she does obtain positive reinforcement of her activities. The system allows her to describe her activities. To

the extent that a nurse can describe what she does, she is better able to learn from her own experience, to mature in her skills, and to teach one who is less skilled. The system gives the less skilled nurse a structure by which to acquire new information. Her progress notes and their deficiencies help to identify her educational needs.

Once the educational needs of each nurse are defined by the system, teaching in depth can be adapted to these needs. Is an in-depth discussion of clinical disorders of calcium metabolism, for example, appropriate for the nurse? Certainly! She is the most likely one to first observe tetany after thyroidectomy (or the lethargy from too much calcium replacement) and she must recognize the problem in order to act.

Ongoing monitoring is needed on each nursing station. While the authors filled this role in this project, a more ideal situation is one in which the head nurse becomes the catalyst for ongoing education, problem identification, and problem solving.

Physician participation in clinical education for nurses is crucial. The physician and the nurse each has experience and viewpoint to offer the other. Each must have easy access to the other at all times and be able to discuss such questions as:

Doctor, what sort of information do you need from the nurse to help care for our patient?

Nurse, what sort of recurring observations do you make in the course of managing a pa-

tient with *diabetes* (or *chest pain* or *hypertension*) that require some decision?

Nurse, what sort of information do you need from the physician in planning for our patient?

Once the habit of collaboration is established, the nurse is less reluctant to question the physician, and the patient is better served. Indeed, when the line of communication between physician and nurse breaks down, errors in judgment often occur at either end.

Finally, we feel that data collection, problem identification, and problem solving are appropriate roles for nurses. These skills should be taught in greater depth at the undergraduate level and the teaching should be continued once the nurse is in practice.

Summary

Three roles of the nurse are described which are often unrecognized by physicians—the nurse as a data collector, as decision-maker, and as patient-teacher.

An educational program was designed to more fully develop these roles in a community hospital. Continually supervised, this program became a primary source of continuing education for nurses, provided great personal satisfaction for the nurse in her daily practice, facilitated nurse-physician collaboration and improved patient care.

Drug Trade Name: Phenaphen—contains phenacetin, aspirin, hyoscyamine sulfate and phenobarbital.

Monitoring Hospital Quality and Productivity

RONALD T. UPHAM, B.S.I.E., M.B.A.* and
NEEN NAMOCK LILLQUIST, R.N., B.S.N., M.N.A.†

CONSIDERING THE delivery of health services, are the terms quality and productivity consonant or antithetical? Quality, the degree of excellence that makes the service reliable,¹ has been an outstanding characteristic of modern health care delivery. However, the influences of several current issues—consumerism, government regulation, increasing involvement of hospitals in malpractice litigation—have brought more emphasis to bear upon the quality of health services.

Productivity, the relationship between the volume of services produced and the input of labor time,² has become a popular topic for discussion and analysis because of increasing labor costs and the shortage (real or imagined) of qualified health manpower. Since the labor component accounts for approximately 60% of total hospital expenses,³ effective staff utilization becomes a prime target in productivity improvement efforts. In the 20-year period from 1950 to 1970, the number of hospital employees per 100 patients had increased 53 percent.⁴ Yet, a manpower crisis is predicted as remedies are sought for the problems of health care accessibility and acceptability.

While many still cling to the concept that productivity is the enemy of quality,⁵ the need to optimize both of these factors is obvious and urgent. One solution to this dilemma could be the use of cost effectiveness analysis—a comparison of alternative ways of accomplishing an objective according to which contributes the most for a given cost or achieves a given objective at the least cost.⁶ In this context, the analysis would determine the method of staff assignment and utilization which achieves the highest quality of service or which achieves a predetermined level of quality at the least labor cost.

This project was sponsored by the Minnesota Hospital Association. It was a component of Northlands Regional Medical Program, Inc., supported by HEW grant #5 GO3 RM-00021. Opinions presented do not constitute endorsement by NRMP, Inc., or the Department of Health, Education and Welfare.

*Director of Management Engineering Division, Minnesota Hospital Association, Minneapolis, Minnesota.

†Director of Education, Minnesota Hospital Association, Minneapolis, Minnesota.

Any attempt to analyze and improve the cost effectiveness of health care must incorporate a measurement mechanism which will simultaneously monitor the significant factors of productivity and quality. The results of these measurements can then be used to determine the optimum relationship between these two factors.

The authors describe here the development and implementation of a voluntary internal information system which periodically measures indicators of hospital productivity and service quality.

Systems Analysis Program

Management engineering, or industrial engineering, may be defined as "the art and science of utilizing and coordinating men, equipment, and materials to attain a desired quantity and quality of output in a specified time and at an optimum cost."⁷ This field includes the techniques and philosophies of method improvement, system analysis, operations research, management science and behavioral science. While the application of management engineering in hospitals dates back to the early 1900's, many persons in the health care industry tended to regard this profession with suspicion and distrust because of the unprofessional activities of "efficiency experts" during the 1920's and 30's.⁸

Industrial engineering concepts have met with more favorable acceptance in the past 20 years due to the influences of rising costs, shortages of qualified personnel, and the public's demand for more services.⁹ More recently, hospitals have pooled their efforts and expertise in this field by forming cooperative, multi-hospital management engineering programs.¹⁰

In 1969, the Minnesota Hospital Association formed such a program, the MHA Management Engineering Division (MED). To maximize results and to avoid the image of the "efficiency expert" who undertakes studies with little knowledge of health care operations, Management Engineering Division services are designed to aid the

institution in achieving improvement through *on-going efforts of its own in-house staff*. This approach is rather unique since most other groups provide management engineering services on a one-time or intermittent basis through a group of professional engineers who are employed by a central agency.

The *MED Systems Analysis Training Program* was developed to train hospital and nursing home personnel in the theory and application of basic industrial engineering techniques such as cost analysis, method improvement, scheduling, job analysis, inventory control, and general problem solving. The principal offering is an intensive, 1-week session designed to prepare students for full-time positions as systems analysis practitioners. Through a one-week Department Managers Workshop, a team approach is emphasized whereby the systems analyst is a technical resource available to management personnel for problem-solving studies of many forms. The analyst's contribution involves the collection and technical analysis of pertinent information, but the appropriate manager retains the responsibility for problem identification and the selection of alternative solutions.

Through five offerings of the Systems Analysis Training Program, Minnesota hospitals and nursing homes, rural and urban, have trained over 40 systems analysts and 250 department managers. One participating hospital, utilizing two full-time analyst positions, generated savings of \$538,900 after analyses of many departments. By projecting this experience to all institutions which have participated, total savings of the systems analysis program can be estimated at 2.8 million dollars over the past three years.

NRMP Project

While the effectiveness of the MED Systems Analysis Program has been proven, there is a pressing need to correlate improved staffing utilization with analysis of quality of care. This demonstration project was undertaken to develop and to implement a system for concomitant monitoring of quality and staff utilization in three Minnesota hospitals: St. Paul-Ramsey Hospital, St. Paul (515 beds); Rice County District One Hospital, Faribault (103 beds); and Glencoe Municipal Hospital, Glencoe (54 beds). Several quality audit and staff utilization systems, as developed by various multi-hospital management engineering programs,¹¹ were reviewed and test-implemented according to the following criteria: (1) accuracy

and reliability; (2) ease of application by systems analysts; (3) ease of maintenance as an ongoing information system; (4) general applicability to most areas of the hospital; (5) acceptability by all levels of hospital personnel.

Quality Audit

The purpose of the quality audit portion of the project was to develop a quality measurement program for the nursing department which could be used as a model for other departments. The program drew heavily from existing methods and developments described in the literature.¹²⁻¹⁶ It should be emphasized that the nursing quality audit is a measure of the total nursing care administered to the patient, not a measure of individual patient care or professional performances by RN's.

Standards from the literature were used as a basis for development of local guidelines for measuring performance. Two examples are as follows:

Nutrition—Fluid & Electrolyte Balance¹⁷

1. Assure proper intake by—
 - (a) giving oral fluids, I.V. fluids, and tube feeding as indicated.
 - (b) withholding fluids when necessary.
 - (c) maintaining an adequate food intake.
2. Assess electrolyte status by observing and recording abnormal signs and symptoms.

Oxygen & Ventilation¹⁷

Measures for providing adequate oxygen and ventilation are—

- (a) encouraging patient to cough, turn and deep breathe.
- (b) checking patency and position of nasal catheter, cannula, or mask.
- (c) checking liter flow of oxygen.
- (d) using proper technique and equipment for suctioning.
- (e) keeping tracheostomy site clean.
- (f) checking respirators for proper functioning.

These Standards for quality patient care were developed by the nursing administration group during the project in one institution, while in another, previously developed Standards were applied. The Standards were made available to all members of the nursing staff involved in their performance.

Audit Committee members were selected from the nursing staff and assigned the responsibility of: (1) constructing and testing a checklist to use when auditing patient care; (2) establishing a routine procedure for auditing; (3) conducting an analysis of the results; and (4) making recommendations to the appropriate department heads.

The systems analyst assisted the Committee by tabulating the results and graphing the quality index.

Audit Checksheets corresponding to local "standards" were developed for the patient record, the nursing care plan, and the patient environment (including direct observation of the patient's care and the patient's opinion of the care). Two examples of audit checksheets from the literature are as follows:

Nutrition—Fluid & Electrolyte Balance¹⁸

	Yes	No	Comment
1. Are oral fluids given, restricted and recorded as indicated?			
2. Are fluid and food within patient's reach?			
3. Are fluids removed from bedside if NPO?			
4. Are I.V. fluids administered correctly (type, rate, labeling)?			
5. Has patient been assisted adequately with eating?			
6. Is the patient receiving the correct diet?			

Oxygen & Ventilation¹⁸

	Yes	No	Comment
1. Has the patient been encouraged to turn, cough and deep breathe at designated intervals?			
2. Is oxygen therapy properly given?			
3. Has the patient been suctioned correctly?			
4. Is the tracheostomy patent and the site clean?			
5. Are respirators used correctly?			

The forms were kept short to facilitate completion in 10-30 minutes and were validated by duplicate audits on the same patient. The inclusion of a "safe level care" question is still under study. This would be used when a high number of "yes" responses were obtained, but one very important factor of quality/safety was missing. A penalty to the score would then be applied.

The *Audit Procedure* included the use of a sampling technique whereby a sufficiently large sample was taken to reflect characteristics of the total situation. Systems analysts constructed random time and random patient selection tables to be used by auditors. Analysts also determined the number of audits necessary to monitor quality care accurately on a continuing basis. Auditors were selected from the nursing staff and trained

to assure consistency of results.

Calculation of the percentage of affirmative answers on the checksheet produced a quality index. This index was graphed for comparison with the indices of staff utilization. This provided a picture of the quality level of patient care and staffing level trends over a period of time.

Analysis of results was conducted by the audit committees. Interpretation of analyses led to specific recommendations for corrective action e.g. initiation or changes in educational and/or orientation programs, supervisory action, change in policies, revision of procedures, re-evaluation of job descriptions, elimination of worksheet questions when continuous 100 percent performance was achieved and addition of new questions as the Standards were strengthened.

Some *Results* of the audit program were surprising. The program produced positive change independent of authoritative decree. Staff auditors upgraded their own performance and that of their colleagues. The "live" in-patient audit generated a high level of interest and all levels of nursing personnel participated. Specific identification of weaknesses enhanced the planning of educational programs for both the staff and the patients. Evaluation of the effectiveness of educational programs, supervision, and assignment of personnel to patients was improved.

Staff Utilization

The purpose of the staff utilization portion of the project was to develop and test a tool for measuring and controlling hospital productivity in accordance with quality standards developed through the quality audit. Two existing hospital wide staff utilization systems were installed and evaluated in the three hospitals. Termed staffing methodologies, these systems set forth a procedure for measuring and predicting the level of staffing required to perform each department function.¹⁹ The methodologies define all significant tasks performed by hospital personnel, and indicate the standard time which should be required to complete each task.

A standard time may be defined as *the time to complete a unit of work when performed with a given method at a prescribed rate of work, with provision for unavoidable delays, fatigue, and personal time.*²⁰ Generally, a standard time is determined by observing and recording a representative time to complete a task, adjusting that time

HOSPITAL QUALITY AND PRODUCTIVITY

o the normal rate of work (rating), and adding an allowance for personal time, fatigue, and delays. Staffing methodologies qualify standard time values by specifying the method and type of equipment used in the task. In some cases, several standard times will be listed for a single task in order to accommodate alternative methods and equipment.

Figure 1 shows a typical standard development worksheet from a staffing methodology. Standard hours per unit of workload are shown for tasks performed in the medical records department. During implementation of the system, the frequency of occurrence of each activity is counted for a base period of time, usually 28 days, and recorded under "quantity for period." (The representativeness of this frequency of occurrence data is checked by examining annual records, seasonal fluctuations, etc.) Multiplying the "standard hours per unit" by the "quantity for period" yields the total standard time required to complete the workload for each activity during the base period. Staffing for these activities is considered variable; that is, staffing requirements fluctuate in accordance with increases or decreases in the workload.

The standard time for all variable activities in the department is totaled and then divided by the single indicator of workload volume—in this case, number of discharges in the base period.

Most methodologies also include a section for calculating the staffing requirements for constant workload activities such as supervision, clerical, in-service education, etc. The workload for these activities is fixed during the short run and the appropriate staffing level is usually determined by hospital policy. For this reason, standard hours of staffing for the constant workload are not given in the methodology; instead, typical staffing hours per calendar day are used.

Once the base period data and calculations have been completed, this information can be used in future reporting periods to assess staff utilization and to predict future staffing requirements. At the conclusion of a reporting period (usually 28 days), the number of workload units completed by each department is counted and recorded. Multiplying the workload units by the standard hours per unit yields the total staff time required to complete the variable workload. Similarly, the calendar days in the reporting period

Standard Development Worksheet—Medical Records					
I. Variable Workload					
Activity	Standard Hours Per Unit		Quantity for Period		Standard Hours Required
A. Discharge Processing					
1. Coding (ICDA)					
a. Set-ups	.026	×	480	=	12.48
b. Processing (discharges)					
1. New Born	.014	×	48	=	0.67
2. Obstetric	.029	×	50	=	1.45
3. Medical	.037	×	222	=	8.21
4. Surgical	.033	×	160	=	5.28
F. Total Variable Hours Required					
Base Period				=	714.4
G. Total Discharges—Base Period				=	502
H. Variable Hours/Discharge (F ÷ G)				=	1.42
II. Constant Workload					
A. Supervisory				=	175
B. Clerical				=	80
C. Inservice Education				=	5
D. Total Constant Hours—Base Period				=	260
E. Total Calendar Days—Base Period				=	28
F. Constant Hours/Calendar Day (D ÷ E)				=	9.29
III. RMS Standard = Variable Standard + Constant					
1.42 hours discharge × _____ discharges/reporting period				=	_____
				+	_____
9.29 hours/calendar day × _____ calendar days/reporting period				=	_____
RMS Standard				=	_____

Figure 1

multiplied by the constant hours per calendar day will yield the staffing requirement for the constant workload. This calculation for the medical records department is as follows:

$$\begin{aligned}\text{Staffing Hours} &= 1.42 \text{ hours/discharge} \times 550 \text{ discharges} \\ &+ 9.29 \text{ hours/calendar day} \times 28 \text{ days} \\ &= 1,041 \text{ hours}\end{aligned}$$

This standard time can then be compared to the actual staffing time which was used during the period to determine staff utilization performance. Staffing levels can also be predicted by estimating the workload for a future period and applying it to the above formula.

During the project, the staff utilization methodologies were installed simultaneously with the quality audit. In each test site hospital, the methodologies were introduced first to administrative personnel and then to department managers. Local staff Systems Analysts were given in-depth training in the various work study techniques required to install the methodologies. During the installation period, it was necessary for the analyst to review all tasks in each department to insure that the method and equipment were the same as that used in the methodology, to evaluate the reasonableness of the standard time values, and to identify any tasks which were not included in the methodology. Much of the workload volume data was collected and recorded by department managers during the base period.

After installation of the two methodologies, staff utilization reports were generated in each hospital for approximately three months. Each

methodology was then reviewed and evaluated by the systems analysts and department managers with assistance from members of the project staff. The Resource Monitoring System (RMS), developed by the Hospital Association of New York State, was chosen as the superior staff utilization system since instructions are straightforward, lists of departmental tasks are comprehensive, most of the standard times are applicable, and the format of the report was more useful.

Resource Monitoring System Report

A sample of an RMS periodic report is shown in Figure 2. One variable workload indicator is listed for each department in the second column together with the number of workload units completed during the reporting period. The actual hours of staff time, taken from payroll records are shown in the next column. The calculated standard staffing hours for the period are shown in the fourth column.

Target staffing hours, listed in the fifth column, are provided for use in those departments where particular circumstances negate the achievement of 100 percent staff utilization. For example, departments such as emergency, labor, and delivery rooms typically involve "stand-by" time where staff must be present regardless of the workload level. Similarly, inefficiencies due to an antiquated physical plan and obsolete equipment will reduce staff productivity. In these cases, a realistic target level of hours is estimated by analysts and department managers to reflect optimum staff utilization under existing circumstances. In practice,

RMS

PERIODIC REPORT

HOSPITAL: COMMUNITY PERIOD: MARCH

DEPARTMENT	PRODUCTIVITY UNIT	ACTUAL HOURS WORKED	STANDARD HOURS REQUIRED	TARGET HOURS	UTILIZATION INDEX
TECHNICAL SERVICES	TREATMENTS - 900	772	725	733	95%
ADMITTING	ADMISSIONS - 813	560	565	569	102%
LAUNDRY	POUNDS - 105,600	3230	2800	2957	92%

FROM PAYROLL

FROM RMS STANDARDS

ACTUAL
TARGET

Figure 2

The target hour value is used in lieu of standard hours for comparison with actual hours worked. Comparison of target hours to standard hours is also used as a basis for setting phased goals for improving the hospital system.

The staff utilization index for each department is shown in the righthand column. The index is calculated by dividing target (or standard) staffing hours by actual hours used. Thus, a 100 percent utilization index indicates that actual staffing hours equaled target (or standard) hours; an index of less than 100 percent indicates an overstaffing situation, and an index of greater than 100 percent reflects understaffing.

Correlation of Quality Index with Staff Utilization Index

Used in conjunction with the quality audit, this index provides the ability to measure quality per-

Figure 3

formance against staff utilization for more accurate decision-making regarding the budgeting of manhours and ratios of categories of nursing personnel. The staff utilization index and the quality audit index can be graphed as shown in Figure 3 to illustrate trends and interrelationships. One test site hospital used standard staffing levels as the basis for manpower budgeting. Six months into the new fiscal year, manpower costs were reduced by over 2% although salaries and average daily census had both increased. Staff utilization for the entire hospital was maintained at 98-99 percent and nursing staff utilization averaged 98 percent. During this same period, quality of service improved and the quality index stabilized between 85 percent and 90 percent. Although not yet applied so extensively, the system has produced similar results in other hospitals. The authors feel that they have sound evidence that hospital quality and productivity can be improved simultaneously and that the described system is an effective tool for measuring and controlling the many variables involved.

Extension of the Systems to Other Institutions

Based upon the information and experience of these investigations, several educational activities were developed to promote more widespread use of the quality audit and staff utilization systems. A 32-hour *Staffing and Quality Audit Workshop* was designed and conducted to train systems analysts and management engineers in components of the system. A two-volume 500 page manual, a Nursing Quality Audit manual, several case studies, and audio-visual aids were developed and reproduced for this course. One session of the workshop has been conducted, and this program will become an integral part of future MED Systems Analysis Training Courses.

The section on Nursing Quality Audit has been presented to two groups of Directors of Nursing and will be made available for separate workshops to groups interested in developing or improving systems of nursing audit. Copies of the Nursing Quality Audit manual were distributed to all MHA member hospitals and nursing homes.

Conclusion

A system for monitoring quality of nursing care and staff utilization has been developed, tested and applied in Minnesota hospitals.

With proper installation and judicious maintenance, this system can provide the following benefits to all such institutions:

- Periodic control of quality and productivity.
- Evaluation of the interaction of quality and productivity.
- Improved cost effectiveness of health services.
- Accurate manpower scheduling and budgeting.
- Objective reimbursement based upon meas-

ured indices of quality and productivity.

Efforts to improve health care quality and productivity can be complementary, and can be undertaken simultaneously. The Minnesota Hospital Association will continue to provide manuals, workshops, and training programs to extend the use of this system.

Patient Education in A Health Sciences Center

DOROTHY VERSTRAETE, M.S., R.D.* and MANFRED MEIER, PH.D.†

THE CONCEPT of patient *rights* is not new. Even in the Fifth Century B.C. the Hippocratic oath included this idea. It is probably as old as the patient-physician relationship. What is new is the current controversial discussion by both lay and professional groups concerning the consumer's fundamental right to optimum health care and to participation in that care.

Responsibilities of the provider to the patient and of the patient as a member of the health care team are becoming more clearly defined. One result is the now widely accepted idea that the patient has the right to make an *informed* decision concerning participation in health care available to him. Health workers must be prepared to assist the patient to arrive at an informed decision. Since patients have a right to information, health workers have the responsibility for providing it.

It is generally accepted that a patient can participate in his own care and make meaningful decisions only if he has a complete understanding of the therapeutic program designed for his needs. However, one of the most conspicuous deficiencies in health care delivery has been the failure to provide adequate patient education programs.¹

This paper emphasizes the value of patient education programs in the care of the chronically ill. Such programs are equally valuable in health maintenance, prevention of disease and in control of acute illness.

Definition of Terms

In considering the patient's right to know, it is necessary to come to an understanding of terms.

Patient *information* means any communication

concerning the patient's interface with hospital or staff function of a nature more or less applicable to all patients.

Patient *instruction* means a communication to a patient or group of patients designed to deal with a particular problem. It usually consists of a transfer of a body of facts designed to provide basic understanding of a disease and of a therapeutic program. It is often informal.

Patient *education* means a structured, interdisciplinary program developed to meet the broad needs of an individual patient. It requires assessment of total patient needs, including an understanding of social, psychological, educational, socioeconomic, vocational and cultural characteristics of the individual. It includes assistance in the development of patient motivation and the initiation of behavioral change. Since cost-benefit considerations have become increasingly important, business administration skills should be utilized in the design and implementation of the program.

For the purposes of this study, the *patient* is defined as the consumer of health services in the hospital or clinic setting. The *whole patient* includes relationships to family, community, employer, and health care provider.

The ideal of optimum patient education requires individualized programs which enable each patient to accept and participate in a health care plan employing the best therapeutic efforts of all members of the health care team.² In the past most patient education programs fell far short of this goal and provided, at best, simple programs of patient instruction.

The Problem

Reliable methods for evaluation of patient education in the delivery of health services have not yet been developed. Peer review methods tend to be too broad and often lack objectivity. High quality health care in major centers has been largely assumed and subjectively expected, but rarely evaluated. Currently, studies are being con-

*Assistant Professor of Food Science and Nutrition and staff source person for the Health Sciences Consumer Health Education Committee at the University of Minnesota.

†Coordinator for Allied Health Programs, Office of the Vice President for the Health Sciences, University of Minnesota. This project was sponsored by the Health Sciences Center of the University of Minnesota. It was a component of the Northlands Regional Medical Program, Inc., was supported by HEW grant #5 GO3 RM-00021. Opinions expressed present those of the authors and do not imply official endorsement by Northlands Regional Medical Program, Inc., or the U.S. Department of Health, Education and Welfare.

ducted to develop objective methods for evaluation of quality health care. Measurement of patient understanding will result in increased interest in the design and evaluation of education programs as a vital component of patient management.

Patient education has carried a low priority within the total context of therapeutic programming, even when it was known that the patient with a chronic disease could not carry out effective self-care unless he clearly understood his role in the management of his disease.³ If *compliance* with instruction is accepted as the measure of the effectiveness of patient education, past efforts at communication were clearly ineffective. An extensive review of the literature in 1969 demonstrated that a range of from 15 to 93 percent of instructed patients were reportedly noncompliant.⁴ Recent studies of diabetes treatment show that acceptance and implementation of programs for self-care can be as low as 10 percent.⁵

The very rapid advances in scientific medical knowledge in recent decades often resulted in focusing attention on pathology rather than on the *patient as a person, suffering from a disease*. Educational emphasis is now broadened by inclusion of social and behavioral sciences in medical school studies, but "there continues to be a serious lack of actual consideration of these factors as they relate to patient education in the practice of medicine."⁶

Even with this broadened understanding, the patient's life situation seldom has been studied as a preliminary to planning. Very little attempt has been made to arrive at reliable individual patient assessment. Unless the patient's psychosocial, economic, educational and vocational profile is provided for the instructional team, the educational program cannot be tailored to the individual patient's needs. Difficulties in following the program then become insurmountable, and patient compliance suffers.

Realistic goals of therapy for the individual patient can only be set after careful consideration of the best approach in relation to individual capabilities. The degree of difficulty for the patient in implementation of the plan for self-care has been shown to affect directly the level of compliance.⁷

Since past patient-health professional communication constituted mere instruction, only the compulsive, well-motivated, intelligent, or deeply concerned patient achieved optimum self-care.

Increase of knowledge from well designed patient education programs has been demonstrated in a few studies. In at least one study, patient knowledge of the disease (diabetes) was inversely proportional to the degree of control of the disease.⁵ Could this mean that plans of therapy were inappropriate, that vital aspects of an education program were ignored, or that patients with the uncontrollable manifestations of the disease had stronger motivation to become better informed?

One problem in evaluating results of patient education is measurement of changes in behavior of the patient. Another is measurement of the reduction of morbidity and mortality through self-care. These desired outcomes are very difficult to assess. Measurements require long term observation of valid sample groups. Compilation of clinical data must be correlated with study of patient behavior in his life situation.

An increasingly important parameter of evaluation is reduction of cost of the delivery of health care by effective patient education. When reduced morbidity and mortality can be demonstrated as a result of patient education, cost reduction to the patient, his family, and the community can be assumed, but is still difficult to measure. One study discussed by Scott Simonds,⁶ was conducted at St. Peter's Hospital in New Brunswick, New Jersey. This study confirmed reduced hospitalization for congestive heart failure following patient education.⁸ Another study conducted at Los Angeles County Hospital demonstrated reduced morbidity of diabetes as a result of education and continuing support provided by a medical team.⁹ Other studies from Loma Linda, California, Dade County, Florida, and the University of Wisconsin have pointed to the same conclusion.

In analyzing traditional programs in order to eliminate past defects from new designs, it becomes apparent that it is important to assess the teaching skill of the professionals involved. The development of programs for patient education by health professionals other than physicians and nurses is an evolving process. Historically, the physician was the principal source of information and support for the patient in spite of the fact that training as an educator was not part of his background. A host of supportive skills now available from many other health specialists can be used to upgrade the education process. Skilled educators can plan with the interdisciplinary team

to implement more effective patient education. Time commitment by physicians can be reduced, while quality is increased.

The Plan of Action

The need to revise and strengthen patient education at the University of Minnesota Medical Center was identified in 1972. The philosophy of interdisciplinary cooperation accepted by the administration of Health Sciences and Allied Health resulted in planning for revision and expansion of patient education at the University of Minnesota Health Sciences Center. In this planning specific attention was given to the following areas:

1. Information gathering: Study of staff, patient load, patient need, quality of existing programs.
2. Interdisciplinary course development and evaluation of pilot courses planned in 1973 and available in 1973-74. Study of possible core curriculum for allied health disciplines.
3. Redesign of units of patient education, with interdisciplinary support being given in the design and evaluation of pilot education units developed in response to identified patient needs.

Information Gathering

The 1973 program and progress reported here was designed to collect data on:

- a. Present staff involvement in patient education.
- b. The Medical Center's patient population.
- c. Present programs in relation to generally accepted standards of excellence, including evaluation of staff.

A survey instrument was developed to obtain information on staff time directed to patient education, and to study preparation and attitudes of both students and staff. The groups to be studied included senior students in the Allied Health disciplines and sample staff groups in the Medical Center. Senior students in the Allied Health disciplines were surveyed in May, 1973. Staff surveying is scheduled to begin in July, 1973. These data will reveal the level of preparation for teaching as well as attitudes of students and staff toward patient education as part of total therapy in individual specialties. They will also reveal the percentage of time allocated to teaching by the various practicing health professionals.

Experience shows that all education is expensive in staff time. Most health care disciplines have some commitment to patient education but the exact amount of staff time expended has never been precisely tabulated. An estimation of the present commitment to patient education will provide a budgetary base for designing improved in-

terdisciplinary programs. Since the recent surge in hospital costs severely restricts funding of new programs, it is hoped that coordination of current staff commitments will permit development of improved programs without greatly increased budgetary support.

The survey will also evaluate attitudes toward, and preparation for, patient education by various types of personnel. In future patient education programs persons should be selected who have the skills and positive attitudes which enable them to function as educators.

More accurate information is needed to plan education programs and educational tools which suit the socioeconomic, educational, ethnic and cultural characteristics of the patient population being served. Under the leadership of the faculty in Health Education (School of Public Health) but still within the interdisciplinary framework, methods were developed for compiling information on the patient population in University of Minnesota hospitals. Much of this information is already being collected in some form in patient records, but development of a method for standardizing and compiling information from multiple sources required cooperation of hospital administration, the hospital admissions office, medical records personnel and the business office. Compilation of information by this method is scheduled to begin in September, 1973.

Evaluation of present programs in relation to generally accepted standards of excellence poses a difficult problem. The first effort is being directed toward *identification* of existing programs. Many of these programs are informal, often provided on a one-to-one basis, and not necessarily offered to every patient with a given diagnosis. As a consequence, a complete list of programs is difficult to obtain. Preliminary investigation showed that the only possible approach involves personal interviews with hospital staff personnel in all clinical areas.

The survey will be employed to identify those teachers who have participated in programs which meet accepted standards of excellence described in *A Model for Planning Patient Education*.² Collected information will be used to evaluate the quality of current patient education programs.

Interdisciplinary Course Development

The need to strengthen the preparation of health workers as patient educators was apparent after cursory analysis of curricula in Allied Health dis-

ciplines. Very few disciplines require appreciable basic academic course work in education, even in specialties where patient teaching is already considered a vital part of therapy (e.g. medicine, dental hygiene, dietetics, and nursing).

Two courses were designed to supplement the backgrounds of a wide variety of health specialists. The first, *Interdisciplinary Approach to Patient Care*, will be available 1973 fall quarter to junior and senior students in health disciplines. The second, also being planned on a cooperative basis, is *Problems in Patient Education*. Material and approaches included in these courses were selected with two purposes in mind: to supplement undergraduate preparation, and to strengthen backgrounds of the practicing professional. Both courses will also have value in programs of continuing education for health workers.

Redesign of Units of Patient Education as an Interdisciplinary Effort

Progress toward this objective must await completion of information gathering studies. Commitment of many disciplines to interdisciplinary patient education will require hard data as well as firm persuasion. This is a future objective which has not yet been approached.

The process of implementing change in a large institution is slow and difficult. The usual problems in achieving change involve facilitation of communication and effort through group process to reach a common goal. Although personnel in a complex organization tend to follow strong leadership from within their own peer group, they will act in response to administrative directives. Institution-wide planning for effective patient education will require deliberate support from hospital administration. Medical staff, allied health professionals and subprofessionals may be expected to participate in varying patterns, depending on the strength of program incentives. The new Health Sciences Center with its widespread support has the potential for stimulating academic programs and professional practice to be supportive of each other in working toward higher standards of excellence. The beneficiaries will be the patients, because of improved delivery of health care, and the health professional, because of

achievement of higher levels of competence

Summary and Discussion

Current interest in patient rights and responsibilities has accelerated reappraisal of the contribution of patient education to quality of health care. Evaluation of traditional patient education programs in hospital and clinic settings, when attempted at all, revealed marginal levels of patient understanding and compliance and passive patient role expectancies by health professionals.

Effective improvement of health care can be facilitated by patient participation as an active member of the health team. Evidence suggests that patient education programs can reduce morbidity and mortality when they take into consideration the multiplicity of facets of the life situation which affect each patient's therapeutic efforts. Higher quality of care and lower costs to both the patient and his community constitute rational and achievable objectives.

Plans have been completed for study of coordinated interdisciplinary patient education at the University of Minnesota Health Sciences Center. Health Science leadership groups are committed to developing innovative patient education programs with the realistic assumption that such efforts will improve the quality of health care. The need for objective evaluation of such programs is acknowledged.

A method of gathering data by surveying staff participation in patient education is developed and operational. Information on time allocation, attitudes, and level of preparation for teaching will be obtained.

A method for obtaining and compiling data on characteristics of the patient population has been designed. The direction of pilot programs for patient education will be obtained from this information retrieval system. Educational materials and multilevel approaches can only be developed when pertinent information is available.

The clearer understanding of problems in patient education will influence curriculum changes and plans for continuing education, in order that health professionals will achieve the competency required for this responsibility.

Peer Review of Patient Care in Nursing Homes

DENNIS LAYER, M.A.* and JENEAN ERICKSON, R.N.†

IN THE FALL of 1971, Senator Moss of Utah chaired a session of the select subcommittee on Long Term Care. Many persons came forward to testify concerning the inadequacy of nursing home care.

Shortly, after this hearing the Board of Directors of the Minnesota Association of Health Care Facilities voted to restructure the ethics committee of the Association into a peer review committee. The function of this committee was to investigate the complaints brought before the Senate subcommittee to determine the extent of truth contained in the allegations.

The persons selected to serve on the first peer review team included administrators with a history of excellence in nursing home management and recognized leaders in the nursing profession. The teams were organized to include from three to four persons.

Because of the serious nature of the allegations made against many nursing homes, only one ground rule was established for these early surveys. If any indications of patient abuse or criminal neglect were found, the report would be turned over to the Minnesota Department of Health for legal action, and the home's membership in the Association would be terminated immediately.

During these pilot surveys many difficulties were experienced. Because the teams were not adequately trained, communication barriers arose between the surveyors and the staff members of the homes being surveyed. Due to the negative design of the survey checklist, only areas of deficiency could be highlighted. This led to frustration for team members as well as the homes

surveyed. The area that caused the greatest difficulty was the seeming inability to provide the home with what was needed to correct the deficiencies that were uncovered during the survey.

Even though these problems existed, the positive aspects of the peer review program far outweighed the negative aspects. The concept of self-policing and all of its possibilities, including its help-from-within potential, was a strong, driving force to keep the program going.

At this point a search of available literature was made to determine if a model peer review program for long term care facilities existed. Our search led us to the discovery that peer review was virtually untried in nursing homes.

This fact led the Association on a search for funding to develop a formally structured program of peer review.

The objectives of the program were as follows:

1. *To select and train survey teams. The teams were to be trained in survey techniques and communication skills.*
2. *Develop and print a survey instrument that would provide an accurate reflection of the care being delivered.*
3. *Locate and compile a listing of available consultants to assist in the correction of deficiencies.*
4. *Compile, print, and make available a library of written resource material to assist nursing homes in up-grading care.*
5. *Conduct surveys of nursing homes, provide necessary resources, and resurvey these homes at a later date to determine the extent to which this program could affect positive changes in the provision of nursing home care.*

Methodology

The selection of persons to serve on the peer review committee was made by the elected officers of the Association. The criteria for selection was experience in the profession of nursing home administration or nursing, history of accomplishment in Association activities, and a willingness

*Litchfield, Minnesota.

†Chairman of the Peer Review Committee of the Minnesota Association of Health Care Facilities.

This project was sponsored by the Minnesota Association of Health Care Facilities. It was a component of Northlands Regional Medical Program, Inc., supported by HEW grant #5 GO3 RM-00021. Opinions presented do not constitute endorsement of NRMP, Inc. or the Department of Health, Education, and Welfare.

to commit the time and energy necessary to accomplish the objectives of the program.

Two teams of four persons each plus two alternates were chosen to be trained. The training was conducted by experienced personnel from the Minnesota Department of Health, registered dietitians, nursing personnel from the Association, and communications specialists from the University of Minnesota.

The training was conducted over a two-day period. Topics included: survey techniques, health records organization, use of food thermometers and proper food serving techniques, and communication skills. The purpose for including the session on communication was to give the peer review teams additional confidence when meeting with the administrator and going over the results of the survey.

While this training was being planned and conducted, sample survey checklists were being collected from various agencies and organizations around the country. The best features of all the checklists were then put together. The form is reviewed after each survey in order to improve its effectiveness. If the review of the form warrants any changes, these are discussed at meetings of the peer review teams.

It became clear almost from the start that specialists in various health care disciplines would offer many advantages to the peer review program. Contact was established with the Minnesota Medical Association, the Consultant Dietitians Association, the Minnesota Medical Records Association, and the Minnesota Podiatry Association. The program was presented to liaison from these groups. On-call support for assistance was requested and received from each of these organizations. An important aspect of the program would be to develop a file of resource information that could be sent to the homes surveyed to help them correct any deficiencies.

Literature from many sources was sought. Job descriptions, procedure manuals, evaluation forms, health record systems, and safety plans are just a few examples of the types of resources sought. As the resources came in, they were categorized by subject matter. The teams then set about the time-consuming task of assembling and coding the information so that it could be retrieved when needed. This process is continuous as new and better information becomes available.

The survey team now trained, armed with a well-developed checklist and with the knowledge that they could assist the home to correct deficiencies, set out to prove the concept of peer review.

A general meeting of the Association members was held in May of 1972. Homes were asked to volunteer if they wished to participate in the survey process. Nearly 30 homes volunteered to take part. From these, 12 homes were selected to participate in the initial series of surveys. The homes were selected on the basis of type of ownership, size and location. Nine were proprietary and three were non-profit. Six were 70 beds or over and six under 70. Five were located in the metropolitan area and seven homes were located in rural areas or small towns. This mixture of facilities approximates the membership of the Minnesota Association of Health Care Facilities.

The two teams were assigned six homes apiece to survey. Upon the completion of the survey, the teams were to determine the types of resources or consultants needed to assist the homes and schedule the materials or persons as required. After the home received the necessary resource material and was given sufficient time to implement the necessary corrective action, the home was to be resurveyed. At least one member of the resurvey team was to have participated in the original survey of the home. This was done to provide continuity to the survey process but at the same time to avoid any prejudice that may have stemmed from the original survey.

Results

The results obtained from this original effort have surpassed all expectations. From a beginning of 10 trained surveyors the program has reached a stage where last March, 25 additional team members were trained as peer review surveyors. There are presently five teams of trained surveyors performing peer review in every geographical area in the state of Minnesota.

The survey checklist has been refined to the point that properly used, it gives an accurate picture of the care being delivered in the home.

A file has been developed of names of persons from various health disciplines available to offer consultant services to homes requiring such service. This consultation is available on a one-time or longer basis.

The library of written resources has expanded

and now occupies a five-drawer file cabinet at the Association office. The resources are divided into 17 categories from admission agreements to volunteer programs. This material is available to homes that may require it.

To date over 40 member homes totaling in excess of 4,000 nursing home beds have been surveyed. Twenty consultant visits have been made and written resource information has been sent to over 75 homes.

Because of the need uncovered during the surveys, eight seminars in Patient Care Planning, Charting and Documentation have been held. Over 300 nursing home nurses were in attendance at these seminars.

A series of five seminars on Medical Records and Utilization Review were conducted also as a result of the survey data. Over 250 nursing home personnel were in attendance at these sessions. This program was co-sponsored with the Minnesota Department of Health, and cost was underwritten by the regional office of HEW.

Discussion

Based on the homes surveyed to date, the care provided meets at least minimal standards and frequently exceeds this.

The area which is deficient is that of adequate, efficient documentation. Often an outside professional can offer tools to assist in this area. This seems to suggest the need to carefully evaluate the amount of regulatory documentation required in an effort to allow professionals to concern themselves directly with quality patient care rather than extensive paper work.

We also feel nurses in the long term care setting need additional skills to properly administer and supervise the numbers of non-professional workers in nursing homes. The Minnesota Association of Health Care Facilities HEW grant, to train inservice training coordinators, is an excellent beginning in an area that is definitely needed. It is our hope to expand upon this education and continue to meet the ever changing needs identified daily through new research and development.

Efforts must be made to assist some proprietary facilities to recruit and effectively use volunteers which are recognized as an asset to total care. Concerned citizens have much to offer.

A variety of interpretations by nursing home

surveyors throughout the state have apparently led to some inequities in the survey process. An effort will be made to work with our Health Department in an attempt to make the survey process as uniform as possible pertinent to a specific level of care.

The real plus of the peer review program in nursing homes is the positive efforts to upgrade and assist each other to provide total quality care for the elderly. We are pleased with the concern of many other interested organizations in Minnesota. We wish to acknowledge the concern of the Minnesota Health Department, the Minnesota State Medical Association, the Minnesota State Hospital Association, Conference on Geriatric Care the Joint Religious Legislative Council, the Minneapolis Age and Opportunity Center, Inc., the Select Subcommittee on nursing homes chaired by Mr. Flakne, and many citizens who actively support total quality care for those who reside in our nursing homes. The funded support of the Northlands Regional Medical Program demonstrates their concern.

Summary

During the past 17 months, 40 nursing homes with a total of 4,015 beds have been visited by the peer review teams of the Minnesota Association of Health Care Facilities. Once rapport was established with the administration of the homes, the surveys proved to be quite successful.

Salient problem areas have emerged from the vast accumulation of peer review data. The most frequently deficient category centers on lack of adequate documentation of services provided.

Results seem to indicate that many nurses, although well trained to provide direct care services, are poorly prepared for the increased administrative work load of the nursing home. There is also a genuine need to carefully evaluate the amount of regulatory paper work and documentation required in the nursing home.

The concept of peer review is a viable mechanism for determining the adequacy of care in nursing homes and can be a significant force in establishing the rightful role of the long term health care facility in the delivery of health services to the community.

Improving Rehabilitation through Continuing Medical Education

MARLENE J. DESCHLER, M.P.H., R.P.T.,* LAURIE SONDEREGGER, B.A.†
and GARY T. ATHELSTAN, PH.D.‡

MINNESOTA CONTAINS more rehabilitation services and centers than its surrounding states; however, these services are concentrated in the Metropolitan area and the larger urban areas of the State.¹ There is a need to extend the experience of these centers to outlying areas.²

In the early 1960's Dr. Miland Knapp started continuing education programs in rehabilitation services for physicians in Minnesota cities in the outstate areas under the auspices of the State Department of Health.^{3,4} These programs proved successful and expanded the use of rehabilitation services.

In an attempt to further this expansion, to increase the utilization of the facilities and personnel in smaller cities, and to share the latest information with more physicians, Northlands initiated a program to establish relationships between major rehabilitation centers and community medical resources which would provide consultation, education, or evaluation services to the communities. One of the programs established was a continuing education program presented to the medical staff of the Northfield City Hospital by a physiatrist, Dr. Lloyd T. Wood of the Department of Physical Medicine and Rehabilitation of the Mayo Clinic, Rochester, Minnesota.

The Northfield City Hospital is a municipal hospital in a city of over 10,000 population, located 49 miles northwest of Rochester and 27 miles south of the Twin Cities. The hospital has forty acute beds and a forty-bed convalescent unit. At the time of this study, there were eight general practitioners and an osteopathic physician

on the medical staff. The physical therapy department is large and well equipped, located on the ground floor of the convalescent unit with direct access to a parking lot. It is staffed by a registered physical therapist and an aide, and is open five mornings a week.

It was hypothesized for this study that a well-planned continuing education program for the medical staff would: (1) increase the utilization of physical therapy (P.T.) services; (2) change various characteristics of P.T. treatments; and (3) change the range of diagnoses of referred patients. This report describes the impact of the continuing education program on the use of P.T. services.

Method

After a year of preparation by members of Northlands staff, Dr. Wood and the medical staff of Northfield City Hospital met twice to formulate topics to be presented in the continuing education program. A series of six Monday evening programs were planned and conducted over a nine-month span starting in September, 1971. Topics included sports medicine, rheumatoid arthritis, diagnosis of cerebral vascular accidents, heat modalities and case presentations on such subjects as rehabilitation from fractures. Programs were presented by Dr. Wood and other specialists from the Mayo Clinic. Attendance was good and receptivity by the staff was enthusiastic.

Data on P.T. services were collected from patient records in the P.T. department, the hospital and the convalescent unit.

The study was divided into three parts, labeled Period I, Period II and Period III. The *pre-program component* was designated as Period I and covered twelve months, September 1, 1969 to August 31, 1970. Analysis of data collected *during the program* was designated as Period II

*Formerly Rehabilitation Coordinator at NRMP, is presently Research Analyst at Minnesota Blue Cross/Blue Shield.

†Formerly Research Assistant at NRMP, is presently Research Analyst at InterStudy, Minneapolis, Minnesota.

‡Associate Professor, Department of Physical Medicine and Rehabilitation, University of Minnesota School of Medicine.

This study was supported by HEW Grant #5 G03 RM-00021. Opinions expressed represent those of the authors and do not imply official endorsement by the Department of Health, Education and Welfare, or of Northlands Regional Medical Program, Inc.

and covered nine months, September 1, 1970 to May 31, 1971. Analysis continued for a six month *post-program period*, designated as Period III, to evaluate the persistence of any changes in utilization patterns. Because the three study periods varied in length of time, all comparisons were made by percentages of patients rather than numbers of patients.

The data supplied information on the patient's age, sex, primary and secondary diagnoses, physician prescription for P.T., discharge disposition, and length of hospital or convalescent unit stay. Utilizing a specially developed coding form and a five-digit patient identification numbering system, the data were transferred to punch cards and processed by computer. The patient location at the time of the referral to P.T. determined the designation of hospital patient, outpatient, or convalescent unit patient.

The percentages of hospital and convalescent unit patients receiving P.T. were calculated from the total number of institutionalized patients.

Results

Extent of Utilization of Physical Therapy Services

The total number of patients referred to P.T. did not increase. There was a slight increase in the percentage of total hospitalized patients who were referred for P.T. (from .9% to 1.6%) in Period II but this was counterbalanced by a corresponding decrease from Period II to Period III. There were no changes in the percentages of convalescent unit patients for whom P.T. was ordered.

The source of patient referrals changed. Table 1 shows a 15% increase in the proportion of P.T. patients coming from the hospital between Periods I and II and a 7% increase from Period I to Period III. It also shows an 11% decrease in the proportion of P.T. patients coming as outpatients from Period I to Period II. There was a 4% increase in convalescent unit patients from Period I to Period III.

TABLE 1
Proportions of Patients Receiving P.T. by
Source of Referral

	Total Number	Source of Referral		
		Hospital %	Outpatient %	Convalescent Unit %
I. Pre-Program	209	42	41	17
II. Program	176	57	30	14
III. Post-Program	93	49	29	22
TOTAL	476	49	35	17

Physician use of physical therapy department services changed. Patterns of utilization showed that during Period I, one cluster of physicians were high frequency utilizers of P.T., while another cluster of physicians were low frequency utilizers. It can be seen in Tables 2 and 3 that in relationship to each other high frequency physicians constituted a smaller source of all referrals and actually decreased their number of referrals in Period II and Period III by 24%. Low frequency physicians increased their utilization by 19% from Period I to Period III and provided a majority of referrals in Period III.

TABLE 2
Proportion of P.T. Referrals from Physician Clusters*

Physician Cluster	I. Pre-Program	II. Program	III. Post Program
High Frequency	59%	53%	35%
Low Frequency	39%	41%	58%

*Percentages do not total 100 since 2% to 6% of patient referrals for P.T. came from physicians who were not on the staff of Northfield City Hospital and did not participate in the continuing education program.

TABLE 3
Percentage Change of Referrals
from Physician Clusters

Physician Cluster	Period I to Period II	Period II to Period III	Period I to Period III
High Frequency	-6%	-17%	-24%
Low Frequency	+2%	+17%	+19%

Characteristics of Physical Therapy Treatments

1. The number of physical therapy visits per patient changed. P.T. services tend to cluster in three visit groupings since orders usually specify three treatments per week.

The greatest change occurred in convalescent unit patients. Data portrayed in Table 4 shows a general increase in the number of visits per patient from Periods I and II to Period III. Over 45% of patients received one to nine visits in Periods I and II but the proportion was reduced to 25% in Period III. Forty-five percent received 10-19 visits in Period III and 20% had 20-29 visits, resulting in 65% having between 10 and 29 visits. In Periods I and II less than one-third received 10-29 visits.

Orders for very long courses of P.T. treatment diminished. In Period I, 8% of convalescent unit patients received over 50 P.T. visits, compared to none in Periods II and III. In Period II, 14% received from 40-49 visits, compared to none in Period III.

TABLE 4

Percentages of Convalescent Unit P.T. Patients in each Study Period by Number of Visits per Patient

P.T. Visits per Patient	Study Period			N=78 %
	I N=36 %	II N=22 %	III N=20 %	
1-9	47	45	25	41
10-19	17	23	45	26
20-29	14	9	20	14
30-39	11	9	10	10
40-49	3	14	0	5
Over 50	8	0	0	4

The majority of *hospital* patients received from one to nine P.T. visits in Period I and this did not change significantly in Periods II and III. *Outpatients* showed no change in numbers of visits per patient except for a decrease in the percentage of patients receiving very long courses (over 39 visits) from 6% in Period I to none in Period II.

2. Physical therapy modalities utilized. Tables 5, 6 and 7 show the most frequently used P.T. modalities in each group for the three periods. Most common P.T. modalities differed among patients from different sources. Gait training was most frequent in institutionalized patients but uncommon among outpatients. Massage, exercise and whirlpool were common in all. Heat therapy was common in hospital patients and outpatients but not in convalescent patients. Evaluation and range of motion were common only in convalescent patients. Orders for exercise therapy increased in all patient groups from Period I to Period II and in hospital patients from Period II to Period III. There were no significant changes in other modalities except that massage decreased moderately in Periods II and III.

The educational program apparently produced little change in the use of the commonest P.T. modalities except for a definite increase in orders for exercise therapy.

TABLE 5

Numbers and Percentages of Most Common P.T. Modalities for Hospital Patients

Modality	I. Pre-Program		II. Program		III. Post-Program

Evaluation	5	8	0	0	4	8
Others	6	10	0	0	16	33
Total	61	99	36	101	48	99

they were discharged home decreased. The percentage of hospital patients discharged home who were to continue as outpatients decreased also. At the same time the percentage of hospital patients who continued P.T. after transfer to the convalescent unit increased to a comparable degree (9%). Thus, more P.T. was completed during hospitalization or continued after transfer to the convalescent unit.

Convalescent unit patients who terminated P.T. while remaining in the convalescent unit increased by 15% in Period III. The percentage of P.T. patients transferred back into the hospital or to a nursing home decreased by 23%. Here too, there was a suggestion that ordered courses of P.T. were part of a consistent plan of treatment.

Average length of stay for P.T. patients in the hospital and in the convalescent unit did not change from Period I to Period III. Thus, the changes in P.T. observed were not associated with longer institutionalization.

Range of Diagnosis of Physical Therapy Patients

The frequency distribution of the top five primary diagnoses did not change materially during the three periods. The overall averages were as follows:

1. Sprains, strains, soft tissue trauma 23%
2. Fractures, lower extremities 19%
3. Cerebral vascular accidents 13%
4. Arthritis and osteoarthritis 8%
5. Osteoporosis 4%
6. Fourteen other diagnoses 33%

There were, however, several significant changes within the "other" diagnostic grouping.

Referrals with "no diagnosis" disappeared and "unclear diagnosis" dropped from 14% in Period I to 2% in Period III. New diagnoses included Parkinsonism, diabetes, cancer and emphysema in hospital patients; meniscectomy in hospital and outpatients; Bell's palsy in outpatients; and osteoarthritis and Parkinsonism in convalescent unit patients.

Discussion

The purpose of the continuing education program was to familiarize the physicians of Northfield with the latest information in the area of physical medicine and rehabilitation. It was hypothesized that the continuing education would increase the number of patients referred for P.T., that the number of physicians using the services would increase, that the kind of P.T. treatments given would change, and that the diagnoses of patients would change. All of these hypotheses were supported except the first.

Data analysis showed little change in the percentage of patients referred to P.T. from the total patient population in the hospital or in the convalescent unit. Outpatient referrals actually decreased. However, there was a shift in the proportion of P.T. referrals by patient source. A higher percentage of total referrals came from hospital and convalescent unit patients. Physicians were apparently more aware of P.T. services for institutionalized patients and completed the therapy before discharge to their homes.

A cluster of low frequency referring physicians of Period I apparently gained useful information from the continuing education and increased their referrals by 19%. The 24% decrease in the cluster of high frequency referring physicians was partially explained by the move of one high frequency referring physician from the community. The continuing education program could also have provided high frequency referring physicians information about more appropriate uses of P.T. and its periods of maximum effectiveness.

The duration and pattern of P.T. treatment orders remained essentially the same for hospital patients. Outpatients terminated treatments earlier, which suggests that the physicians saw P.T. as a form of treatment with a period of maximum effectiveness and that prolonged treatments were not efficient or effective. Convalescent unit patients also had therapy terminated earlier, yet at the same time a higher percentage received a

longer series of visits. This was a major change in the pattern of P.T. treatment visits and appeared to be a shift in the way physicians saw the rehabilitation potential of the older patients in the convalescent unit. This is particularly significant since all patients in the convalescent unit were over 65 years of age in Period III which was not true in Periods I or II.

Exercise is a major therapeutic tool of P.T. and a modality which requires the greatest expertise. Its use increased from Period I to Period II for all patient groups and from Period II to Period III for hospital patients. Even with the drop in percentage from Period II to Period III for convalescent unit patients, exercise was the second most frequently used modality. The increase in the use of exercise indicates that the physicians became more aware of its importance and effectiveness, and that they utilized the skills of the physical therapist to much greater advantage as a result of the continuing education program.

The changes in the patient disposition at discharge revealed a significant shift in the patterns of utilization. Fewer hospital patients receiving P.T. were discharged directly home while more were transferred to the convalescent unit. This suggests that patients went in the convalescent unit for more rehabilitative care which in turn, allowed them to be discharged home rather than to a nursing home or back to the hospital. The data showed that the percentage of convalescent unit patients who were transferred back to the hospital or placed in nursing homes decreased in Period III.

The addition of several new primary diagnoses in Period II suggests that the physicians learned of new ways in which P.T. could be used. The reduction of referrals which came with unclear diagnosis indicates that the physicians came to recognize the importance of the diagnosis in P.T. treatments.

The increased percentages of convalescent unit patients who received more P.T. visits, the increased percentages of the use of exercise, the decreased percentages of convalescent unit patients placed in nursing homes or transferred back to the hospital, and the increased percentages of hospital patients transferred into the convalescent unit point to a change in the physicians' concepts concerning the potential of older patients for re-

IMPROVING REHABILITATION

ponse to P.T. These changes indicate that this was the most significant shift in the pattern of utilization of P.T.

Summary

A continuing education program in physical medicine and rehabilitation for the medical staff of a community hospital was effective in changing patterns of utilization and concepts of physicians

regarding patients' potential response to treatment, particularly for the older population group. Low frequency referring physicians increased their referrals and continued to do so after completion of the education program. Skills of physical therapists were utilized more effectively and physicians referred patients with different diagnoses for treatment, which also persisted into the post-program period.

Automated Categorical Medical Audit in a Multispecialty Clinic

OSKAR P. FRIEDLIEB, M.D.*

CONSIDERABLE PRESSURES have been present for some time to develop performance standards for the physician in much the same way in which engine performance specifications have been developed for engineers and manufacturers. Those pressures have become sharply intensified by an inflationary economy and an increasing involvement of governmental monies in the provision of health care. The concern for how effectively the health dollar is being spent seems to have been focused primarily on the physician, the latter being the single most distinctly discernible member of the "health team." In truth, quality of care has been a vital concern of the medical professional ever since the 1850's when Virchow established the autopsy as the final diagnostic criterion.

It is also true that attempts to provide valid statistical analysis of patient care (beyond such analyses as are provided by birth, age and death figures) had to wait for the arrival of the computer. One of the most outstanding examples of the use of that instrument in the presentation of health care data is provided by the Professional Activity Study (PAS) and the Medical Audit Program (MAP) of the Commission on Professional and Hospital Activities of Ann Arbor, Michigan. While the presentation of data print-out in PAS and MAP does not provide of itself any assessment of care, it makes such assessment possible by comparing performance of record with performance as ideally defined. This "normative" post-hoc evaluation has obvious defects. It is not clear how to arrive at "norms" in diagnostic and therapeutic regimens and common ground often is found to be too limited to be useful. It is also a moot point whether the final benchmark of successful diagnosis and treatment, viz. outcome, is

affected by such studies. There is a real danger that such computer-based "normative" studies will tend to force the practitioner into non-think, practice-medicine-by-the-numbers situation. The logical extreme projection of an effective computerized quality review would be complete control of the practice of medicine by the computer. This has not been shown to be feasible.

To point out such limitations of the method is not to decry the value of audits of outpatient care. Ciocco et al.¹ studied clinical services provided to new patients in medical groups and were able to establish a relationship between performance and qualifications of the physicians involved. Makover² used the review of samples of medical records in the Health Insurance Plan of New York (HIP) to study care provided by member physicians. All of these studies, as well as those by Morehead,³ Lembeke⁴ and Payne,⁵ used evaluation of the process of care to study performance.

This study follows the same basic pattern of process review, but adds the services of an in-clinic computer. It also attempts to look at some of the economics of out-patient care. After being exposed to the PAS-MAP method as an audit tool in the hospital, it appeared worthwhile to explore the same concept in an outpatient multispecialty clinic setting. Out-patient care generally does not lend itself to computerized data gathering and analysis as readily as hospital care. Record keeping in the hospital is more detailed and diagnostic and therapeutic procedures are more extensive. There is a great need to develop methods for outpatient medical audit. The East Range Clinics since 1970-71 has recorded diagnoses (ICDA code) as well as Xray and laboratory procedures (ERC code) for each patient visit. The clinic computer (Honeywell 120) was primarily designed for accounting purposes. Careful programming, combined with physician education, allowed us to store and retrieve information which could be used in the evaluation of ambulatory

*Surgeon, Virginia, Minnesota.

This project was sponsored by East Range Clinics, Ltd. It was a component of Northlands Regional Medical Program, Inc., supported by HEW Grant #5 G03 RM-00021. Opinions expressed represent those of the authors and do not imply official endorsement by Northlands Regional Medical Program, Inc. or the U.S. Department of Health, Education and Welfare.

health care services. Adaptation of the accounting computer to auditing functions depended primarily on programming, storage capacity, and full cooperation of physicians. The importance of the list can hardly be overemphasized if any computer-based analyses are to be meaningful.

Objectives

The objective of this demonstration project was to develop and test a system of out-patient medical audit in this multispecialty clinic which would: (1) provide analyses of the quality and cost of services, (2) Determine the quality of care given to patients, and (3) Develop improved patient care by medical staff education.

Methods

A Medical Audit Committee consisting of five members of the twenty-six man clinic staff was appointed to carry out this study. The committee, consisting of three internists, one obstetrician and one general surgeon, decided to choose ten of the commonest clinic diagnoses for this audit. As a preliminary step the computer department was asked to provide a list of the number of visits for the fifteen most common diagnoses in 1971. The computer analysis provided the following list in order of frequency:

1. Refractive Errors	4127
2. Hay Fever	2786
3. Other Viral Diseases	1915
4. Acute Pharyngitis	1847
5. Chronic Ischemic Heart Disease	1595
6. Other Eczema and Dermatitis	1487
7. Diabetes Mellitus	1396
8. Acute Nasopharyngitis	1331
9. Cystitis	1321
10. Essential Benign Hypertension	1190
11. Otitis Media	1175
12. Acute Tonsillitis	1202
13. Acute Bronchitis	974
14. Diseases of Sebaceous Glands	959
15. Asthma	865

In selecting the ten most common diagnoses for study, five of the above list were eliminated because meaningful performance criteria would be difficult to establish. Refractive Errors was eliminated for obvious reasons. Other Viral Diseases was thought to be too vague to allow analysis. Other Eczema and Dermatitis was eliminated on the same grounds. Diseases of Sebaceous Glands was considered too trivial for review. Acute Pharyngitis and Acute Nasopharyngitis were lumped together as one diagnosis. The revised

list of the ten most common diagnoses for study with the number of visits was as follows:

1. Acute Pharyngitis & Nasopharyngitis	3178
2. Hay Fever	2786
3. Chronic Ischemic Heart Disease	1595
* 4. Diabetes Mellitus	1396
* 5. Cystitis	1321
6. Acute Tonsillitis	1202
* 7. Essential Benign Hypertension	1190
* 8. Otitis Media	1175
* 9. Acute Bronchitis	974
* 10. Asthma	865

*Study results presented in this report.

On further study, the committee found Acute Tonsillitis, Acute Pharyngitis, and Acute Nasopharyngitis to be entities in which proper diagnosis and management could run the gamut from doing nothing to performing numerous tests and giving numerous medications. It was decided to drop these entities from the study. The study of Hay Fever is still in process at the time of this writing. The seven remaining diagnostic categories were reviewed completely and are reported here.

In order to provide analyses of the quantity and cost of services for these eight study diseases, the computer was programmed to provide data on the service and charges for all patients during 1971.

To determine the quality of care given to patients, the explicit-process method was used.⁶ The Medical Audit Committee developed criteria for minimum professional performance for each of the study diagnoses and estimated the percentage of cases which should show performance on the clinic record. Initially it was thought that non-computer input could be provided entirely by trained non-medical personnel. When this was tested by a series of duplicate runs, the need for physician evaluation of medical records was convincing. Professional review was necessary to interpret the variations in quality and method of recording by staff physicians. The final result was that about ten percent of the clinic records had to be reviewed by physicians. Methodology employed in this study constituted an initial effort at quality review and was therefore not as extensive as might be desired since considerably more is involved in patient care than reflected in the chosen criteria.

Since this out-patient audit was essentially a new venture, reference materials from other reports were not of much assistance. "Norms" of the Metropolitan Health Care Foundation⁷ were

available but not very helpful. The criteria in the "norms" were developed with a view to determine allowable reimbursements for diagnostic and therapeutic regimens while the concern of this study was whether minimum professional performance criteria were being met by members of the group. Criteria developed by B. C. Payne⁵ are hospital oriented and thus not readily applicable to this Clinic.

The Medical Audit Committee circulated written reports to all members of the clinic giving results of each component of the study. Thus individual clinic members were able to observe the relationship of performance data to the expected performance criteria established by the committee. This resulted in a self-evaluating effort on the part of physicians and represented a significant educational effort. Continuing education programs were presented regularly both at the clinic and at the Virginia Community Hospital based in part on the results of these audit studies.

Significant educational benefits occurred indirectly from the process itself. The five-member audit committee learned the process of setting criteria. As each diagnostic category came up for review, members of the committee would ask themselves and each other what constituted minimally adequate workup and minimally adequate management. Informal discussions among other members of the clinic also constituted a type of "Hawthorne effect"* of continuing education.

Results

Tables 1-7 show results of the audit studies. The columns entitled "Actual Data" show results of analyses of actual performance at the clinic. The columns entitled "Expected" show Performance Criteria percentages approved by the Medical Advisory Committee. Service data provide a profile of clinic services for study diagnoses during the entire year of 1971. Performance data show the extent to which the clinic functioned according to expected criteria. For the four chronic diseases there was an overall average of 2.7 visits per patient for the year, and 48.3% of patients were seen only once. For the three predominately acute diseases, visits per patient averaged 1.4 and 76%

*The phenomenon of independent behavioral or attitudinal improvement which occurs because a new study or demonstration has been initiated. It was originally described in industrial engineering research.⁶ In Medicine, clinical trial of a new therapeutic modality often produces a "Hawthorne Effect"—a benefit above and beyond that which is later determined to be the limit of specific response to the therapeutic agent.⁸

were seen only once. Charges for care of chronic diseases were somewhat higher than those for acute diseases, as might be expected from the lists of criteria of performance.

Comparison of data with expected performance shows that in most instances the 26 physicians practice according to the estimated standards of the Audit Committee. Committee expectations were somewhat higher than actual performance for most criteria, paralleling experience of similar audit studies of hospitalized patients. Significant differences were demonstrated in diet prescriptions in Diabetes; Culture, Sensitivities and Follow-up in Cystitis; laboratory tests in Hypertension and Asthma; and History and Chest Xray in Acute Bronchitis.

Discussion

The greatest need pointed up by this study is the development of better record keeping. The out-patient record is notoriously sketchy. We are reorganizing clinic records and hope to use the computer to provide an on-going problem oriented list for posting appropriately on the chart.

It is not possible to determine the impact of this study quantitatively. Preliminary data suggest that the study has had some effect in improving clinic records, but definitive information will require repeat audits. It is our intent to repeat the review of the categories studied after a one to two year period. Physician interest and acceptance have been good. The reports of audit results for each diagnosis (distributed in letter form) produced lively discussions.

Cost analysis yielded some interesting figures. The out-patient management of chronic diseases such as chronic ischemic heart disease or diabetes mellitus has a physician related cost of \$40 to \$50 a year. Acute diseases with cure as the medical outcome objective, such as cystitis and otitis media, cost the patient between \$14 and \$25 for

each episode. This may approach the irreducible minimum in the management of the acute conditions, but increased use of home care conceivably could reduce the average number of annual clinic visits in the chronic diseases.

As to hospitalization, the average daily charge for hospital stay in Minneapolis at the end of March 1973 was \$117.52.⁹ Comparing this with the cost of ambulatory care, further attempts at expanding out-patient services appear to be in order. It seems likely that more frequent clinic and home care visits with closer control of chronic disease states could reduce the amount of hospitalization.

Certain inadequacies of computer evaluation have become apparent. These are primarily in aspects of diagnosis and treatment which are not readily amenable to codification. Such things as the recording of breath sounds or familial history of diabetes are beyond the present capabilities of our computer and may never be feasible or worthwhile.

It was found that while the computer had a definite place in audit of out-patient care: in determining incidence of disease categories, in reporting the quantity and costs of services, and in

the retrieval of appropriate charts. Detailed analysis of quality performance still depended on manual chart review. It is conceivable that more formalized record keeping could render audit more automated. However, it appears that the significantly fewer numerically identifiable indices render out-patient clinic practice less amenable to computer-based audit than hospital practice.

Summary

An effort to conduct a computer-based medical audit of the explicit-process type in a multispecialty out-patient clinic setting was successful to a degree. Criteria were set by a committee of staff physicians. The computer was found to be most valuable in determining incidence of disease categories and in retrieving services and cost data. Manual review of records, while still essential, was made manageable by use of the computer. Cost analysis in acute disease categories suggested that the outcome of "cure" was probably reached in minimum number of visits. The audit process lively staff interest in audit reports and audit-based continuing medical education sessions, provided mechanisms for improving the quality of patient care.

An Outpatient Medical Audit

A. STUART HANSON, M.D.* and EDWARD D. KRAUS, M.D.*

THE MEDICAL AUDIT is an established method of comparing actual care as recorded in a patient's medical record to a group of standards developed independently. Comparing actual performance to preset standards can provide objective assessment of the "quality" of care provided. This process has been used extensively in the hospital setting. The major objective of this project was to develop a system of auditing outpatient medical records at the St. Louis Park Medical Center. It was hoped that the full medical audit cycle of demonstrating deviations and insufficiencies in a non-punitive manner would be educational for individual physicians and for the group as a whole.

Although evaluation of outpatient medical services by the medical audit process have been attempted previously, few published studies complete the full audit cycle within one organization where all physicians have mutual responsibilities to each other. The Commission for Professional and Hospital Activities has a limited outpatient medical audit which is best adapted to outpatient clinics of hospitals.¹ The National Ambulatory Medical Care Survey, a study in progress directed by Kerr L. White, is attempting to analyze ambulatory care visits from a sample of physicians from the entire country.² The University of Minnesota sponsored a conference in March, 1968, entitled "Outpatient Care Audit" in which programs at the University of Minnesota, Yale University, and St. Vincent's Hospital in New York were outlined.³ Many studies have been aimed at quality control of outpatient care, and some of these have used audit procedures in collecting information.⁴⁻⁷

The St. Louis Park Medical Center is a 75 physician multispecialty clinic serving over 200,-

000 patient visits per year and maintaining about 250,000 patient records. The records contain entries concerning ambulatory care and summaries of acute hospitalizations. With an obligation to provide quality care to this patient population, we felt it was important to develop some method of evaluating the effectiveness of the care provided.

The specific objectives of the audit project were: (1) to involve many clinic physicians in choosing diagnoses for study, in developing "Master Criteria" patterns and in setting *Expected Performance* standards of care, (2) to develop systems for chart abstracting and data processing, (3) to develop a manual to provide direction for non-physician auditors, (4) to use non-physician paramedical personnel as auditors for chart abstracting, (5) to make the audit detailed in scope, (6) to develop a statistical analysis to evaluate reliability and validity of the abstracting method by paramedical personnel, and (7) to integrate the audit into ongoing professional standards and educational programs at the Medical Center.

The outpatient audit, like many hospital audit processes, was a retrospective analysis by review and abstraction of clinical records at least three months after the initial patient visit. This conventional approach compares data recorded in the clinical record to a set of standards called "pattern criteria" for each specific diagnosis. A major difficulty with outpatient care evaluation is the multiple entries in the record which document patient services over a significant period of the patient's life. The record reflects the interaction of many disease processes and often excludes much of the data from hospital episodes of acute decompensation. Data recorded by many different persons show varying degrees of completeness and are loosely organized chronologically. The various types of data (e.g., laboratory, Xray, and visits to various departments) are inserted in separate sections of the record and present difficulties for coordination. Fortunately legibility was not a problem since most progress notes at this Center are typewritten.

Methods

Twenty Study Diagnoses were chosen by requesting each of fourteen clinical departments to suggest three diagnoses to be evaluated. From this list twenty diagnoses were selected by the physician coordinators, which reflected the following characteristics: (1) crosses specialty and subspecialty lines, (2) includes all age groups, (3) includes medical and surgical problems, (4) includes acute and chronic illnesses, and (5) includes simple and complex problems. The list of the 20 selected diagnoses is as follows:

1. Hypertension
2. Diabetes mellitus
3. Duodenal ulcer
4. Iron deficiency anemia
5. Conjunctivitis
6. Carcinoma of the lung
7. Chronic sinusitis
8. Rheumatoid arthritis
9. Benign ovarian neoplasm
10. Pneumonia
11. Ulcerative colitis
12. Colle's fracture
13. Cystitis
14. Pyelonephritis
15. Corneal abrasion
16. Otitis media
17. Nontoxic nodular goiter
18. Depression
19. Asthma
20. Basal cell carcinoma

Pattern Criteria were developed for each of the 20 diagnoses. Two or three physicians on the Medical Center Staff were asked to list the optimal information that might be recorded for that diagnosis under the following categories: (1) historical information, (2) physical examination, (3) laboratory data, (4) therapy, and (5) followup. Physicians were specifically chosen to provide diversity of viewpoints (e.g., medical vs. surgical, adult vs. pediatric, general vs. specialized). A "Master Criteria" pattern was prepared for each diagnosis by physician coordinators after synthesizing the two or three individual pattern criteria. The process involved 51 clinic physicians and was accomplished without formal committee meetings; most communications were completed by memorandum. Once "Master Criteria" patterns had been developed, the broad limits of data to be abstracted from medical records could be defined.

A "Case Abstract Form" was constructed to allow tabulation of data in a form that could be easily transferred to punch cards and electronic data processing equipment. The data were grouped

in broad categories by history, physical, laboratory, therapy and followup. The total data abstracted from each patient record was contained on two standard 80 column punch cards.

An *Audit Manual* was prepared to aid non-physician personnel employed to abstract patient records. The manual explains coding of information such as physician, department, diagnosis, procedures, laboratory values and the "Master Criteria" patterns for each diagnosis. Paramedical personnel employed to do chart abstracting were all familiar with the organization of our medical records and record room procedures. Auditors included nurses, licensed practical nurses, medical assistants, receptionists, laboratory assistants and a premedical student. After initial indoctrination, each auditor abstracted several charts under direct observation of physician coordinators. Physician coordinators resolved all questionable items identified by auditors daily and checked each abstract for completeness. Patient records were collected by diagnosis so that auditors could review a single diagnosis for most of each abstracting session.

Monthly Printouts of I.D. numbers of all patients seen with each of the 20 diagnoses were obtained from the electronic data processing department during the first nine months of 1972. The charts were retrieved from the record room at least three months after the initial visit to allow adequate time for recording followup information and estimation of outcome. Abstracted data were transferred to punch cards, recorded on master tapes and processed by computer on a quarterly basis.

Quarterly Analyses were divided into three components: (1) individual reports to each physician having patients in the study series, (2) summary reports to each clinical department involved, and (3) summary reports for the Medical Center as a whole. Individual physician reports included a summary listing the physician's activity for the prior three months relating to the 20 diagnoses studied. It included all basic data: number of patients seen, types of evaluation, diagnostic findings, management and followup information. During the study three quarterly reports have been completed with letters of explanation to each physician and each clinical department.

Validity and Reliability of abstracted data was analyzed with assistance from the Biometry Division of the University of Minnesota Medical

school. One hundred charts were selected at random by a statistician from a computer printout of chart numbers in ascending order without respect to diagnosis. Seven charts had to be eliminated because they had been erroneously missed in the auditing process. The ninety-three records were reabstracted by the original nonphysician auditor and separately by one of the physician coordinators without knowledge of the original abstract or the other reabstract. The most important or "key" information for each specific diagnosis was selected for the testing process. The resulting three separately performed abstracts for the 93 records were compared as follows: Physician vs. Original; Physician vs. Reaudit; and Original vs. Reaudit. The total number of *Differences* (called "Errors") were listed for each chart, and all of the charts with the same diagnosis were summarized. Errors were subdivided for each of the key pieces of information to determine which kind of information was most often erroneously abstracted. More detailed analyses of Errors demonstrated: (1) the degree of difference in percent of history recorded, (2) Errors per chart and Errors per column for each diagnosis, (3) whether Errors were inherent defects in the design of the case abstract form or due to judgment inadequacy of the auditor, and (4) whether Errors were true omissions or due to recording of excess chart information which was not pertinent to the diagnosis.

Expected Performance standards for the whole Medical Center for each diagnosis were estimated by asking one "expert" Medical Center physician to state an "ideal" percentage of performance for each item in the abstracted information. In estimating "ideal" percentages the "expert" physician was asked to consider all known modifying interactions and circumstances in our outpatient setting. Expected performance percentages were compared with percentage calculations of actual performance for each diagnosis for the Medical Center as a whole and for each department where adequate numbers of patients with that diagnosis had been seen.

Results

Most of the objectives of this project were fulfilled. We were able to involve over 70% of the physician staff in active documented participation in the audit process. A chart abstracting mechanism was developed and nonphysician personnel functioned well in abstracting the data. Data proc-

essing programs and reporting mechanisms were developed and functioned well in the process of detailed outpatient medical audits.

One of the major objectives of this project was to determine the effectiveness of nonphysician personnel as the principal auditors in collecting and tabulating data from patient records. The reliability and validity portion of the study indicated that in areas where a subjective recording was required, there was more variation than in areas where only an objective measurement was recorded. The overall percent of Error for the 93 charts reabstracted is seen in Table 1. If the subjective estimate of percent of ideal history is not included, the percent of Error between the original abstraction and the reabstraction by the same person was only 10.5%, and the Error between original abstraction and physician abstraction was 15%. This means that the auditor agreed with himself or herself about 90% of the time and with the physician auditor about 85% of the time.

TABLE 1

Percentage Error in 93 Reabstracted Charts	
Overall Averages	
Physician vs. Original	16.8%
Physician vs. Reaudit	17.6%
Original vs. Reaudit	15.3%
Averages after Eliminating Subjective History Appraisal	
Physician vs. Original	15.0%
Physician vs. Reaudit	13.4%
Original vs. Reaudit	10.5%

Performance data on all patients with each of the 20 study diagnoses for the entire nine month period were tabulated by clinic department and for the Medical Center as a whole. Tables included the "Expected Performance" percentages for comparisons.

Table 2 presents the summaries of the data for chronic sinusitis. Twenty-four separate items constituted the "Master Criteria" in the management of this disease. The "Expected Performance" estimate is shown in the first column, and actual performance data appear in subsequent columns. Five items are highlighted for review because they varied most significantly from the expected. The validation study included seven cases with this diagnosis. Agreement between physician reaudit and nonphysician audit was better than the overall averages presented previously in Table 1.

The most consistent defect in all of the disease summaries was the lack of record concerning outcome. Those diseases that tend to be most chronic

such as ulcerative colitis, rheumatoid arthritis, nontoxic nodular goiter, hypertension, duodenal ulcer, diabetes mellitus, depression, carcinoma of the lung, ovarian neoplasm, basal cell carcinoma, and asthma all had high percentages of outcome recorded. The more acute diagnoses such as conjunctivitis, corneal abrasion, cystitis, pyelonephritis, otitis media, and pneumonia had lower percentages of outcome recorded. The diagnosis of chronic sinusitis also had a high percentage of outcome not recorded, and it may be that our physicians are using this diagnosis in a way that doesn't fit our pattern criteria.

The large body of information on each of the diagnoses was made available to all physicians at the Center. Data analyses are being used by Medical and Paramedical Education Committees for continuing education programs. The Professional Standards Committee plans to continue using the audit system for an ongoing evaluation of professional activities at the Medical Center.

Summary

An outpatient medical audit system was developed and evaluated at the St. Louis Park Medical Center. Fifty-one of the 75 staff physicians participated in the project. During a nine-month period all patient records with any one of the twenty diagnoses being studied were retrieved for abstraction. A chart abstraction mechanism was developed using nonphysician personnel. A reliability and validity study was completed and indicated that the non-physician abstractors agreed with themselves 90% of the time and with a master audit performed by a physician 85% of the time. Physicians received quarterly reports of their activity with the 20 diagnoses under study. A summary of the data collected on each disease was compared to "expected" performance estimates. The audit information was made available to all Medical Center physicians, and the ongoing audit project is being integrated into the committee structure of the organization.

Community-Based Health Education Councils

A Brave Venture

ROBERT J. WILKINS, M.H.A.*

JUST AS MANY pieces of legislation have had their origins in study commissions,[†] the Community-based Health Education concept can be traced to a special "Commission on Higher Education" which was created by the Carnegie Foundation. It was established out of concern for "... a shortage of professional health manpower, the need for expanding and restructuring the education of professional health personnel and the vital importance of adapting the education of health manpower to changes needed for an effective system of delivery of health care in the United States." In addition to the talent arrayed among its own membership, the Commission tapped a wide variety of other resources in the educational, health and public sectors. Its initial report¹ was published in October 1970.

A priority for health manpower coordination was also cited in the "Millis" report:² *"Initiate the organization of a local system of health science education and interdigitate that system with a regional system of health service."*

The Carnegie Commission Report cited many familiar problems and solutions. One particular recommendation—the establishment of 126 "Area Health Education Centers"—attracted a great deal of attention among educators and health providers. The Federal Government embraced the notion by providing grant and contract monies. An "Area Health Education Center" was seen as serving localities without a health science center, focused at a local hospital with its educational programs administered by a University Health Science Center. Training of medical and dental residents, continuing education for local practitioners and assistance to community colleges in

training health personnel were seen as its roles. Thus came the term "AHEC." Some educators and providers who agreed with the concept took a differing view on its implementation. Namely, that *the initiative should be taken at the community level* with groups of educators and providers organizing and requesting assistance from the Health Science Centers.

Two Federal Agencies became involved. The Bureau of Health Manpower embraced the "AHEC" approach with money contracted to Health Science Centers. The community-level approach was funded through Regional Medical Programs, with various titles attached to it in different regions. In Minnesota this effort became known as "Community-based Health Education Councils" or "CHEC's." Supplementing a special grant with local funds, Northlands RMP was able to start seven CHEC's on August 1st and two additional ones on October 1st of 1972.

Area Health Education Centers vs. Community Based Health Education Councils

The University of Minnesota is one of ten Universities who received an AHEC contract. It focused its attention on the area suggested in the Carnegie Commission Report—Central Minnesota. Its stated purpose is to "improve the distribution, supply, quality, utilization and efficiency of health personnel so as to bring into balance health manpower needs and resources." By coincidence this same area had been one of the first to establish a Community-based Council (CHEC). Result: The CHEC formalized its organization and became the contracting agency for many of the activities of the University of Minnesota AHEC in Central Minnesota.

One of Northlands 1972-73 Manpower projects was situated at St. Cloud State College (largest higher educational institution in Central Minnesota) for development of a "Physician's Assistant" program.³ As a precursor of the CHEC concept, the project specified a clear involvement of physi-

*Associate (Deputy) Director of Northlands Regional Medical Program, Inc.

†The legislation establishing Regional Medical Programs originated in a report by the President's Commission on Heart Disease, Cancer and Stroke (DeBakey Commission), December 1964.

These projects were sponsored by various community organizations. They were a component of Northlands Regional Medical Program, Inc., supported by HEW grant #5 GO3 RM-00021. Opinions presented do not constitute endorsement by NRMP, Inc. or the Department of Health Education and Welfare.

cians with the College in developing the new curriculum, and in providing assurance of future employment for graduates. The program hopes to enroll its first students in the fall of 1973.

The Concept of Community-Based Health Education Councils

The premise, if not the promise, of Community-based Health Education efforts is tied to such questions as:

- Is there any accountability of educational institutions: for the type and numbers of health personnel they produce? for the relevance of curricula?
- Do health providers have a responsibility to guide the production of health manpower in educational institutions according to health service needs? Do they want this responsibility?
- Who should provide necessary manpower for whom? where?—local, regional, state or national basis?
- Will local production favorably affect local supply and distribution?
- Do we need better continuing education for the personnel we have instead of continuing emphasis on producing new personnel?

- Is there any payoff in educating the public in more effective use of the present health care system? the patients in better "self-care"?
- If the voice at the community level is amplified, will the Health Science Centers listen? respond?

The Approach in Minnesota

The Formula

Assist local leaders to get educational institutions and health care providers together in each region of the state. Create only *informal* structures. Facilitate communication in the hope it will lead to cooperation. Present the questions outlined above. Involve each group in its own assessment of needs and solutions, but in a context of "the whole." Provide modest funding, mainly for paid staff. Bring project directors (staff) together at regular intervals. Create a similar structure at each Medical Center in Minnesota to participate in all activities.

Because of its experience and modest success in bringing groups together to attack problems, Northlands RMP proceeded to accept the opportunity for special funding of this experiment in Minnesota. Some may even say we proceeded

Figure

with insufficient caution.

Territory

The defined "planning areas" of the State of Minnesota which are used by Comprehensive Health Planning (b) Agencies [CHP (b)] were accepted for CHEC development. The Figure shows the areas. Table 1 gives area characteristics. At the time the CHEC applications were being developed —

- Five of the planning areas were served by a funded CHP (b) agency with staff. One became the CHEC applicant (C); three gave active support to the development of the application by the CHEC group (A, B and D); one, the seven-county metropolitan area, applied and then withdrew because of higher priorities of its other work programs.
- Three of the planning areas were not funded or staffed as CHP(b) agencies (E, F and G), although two of these had applications for funds pending in Washington. The Southwestern CHEC (E) was organized under the aegis of a community-action group which had its origin in OEO. The Southeastern CHEC (F) was organized under an independent aegis but with participation and support by both the voluntary planning agency and Mayo Institutions; the South Central CHEC (G) was organized by a group that was also conducting discussions for organization of the CHP(b) agency. (It now appears that the CHEC group will give im-

petus to the development of a regional commission and CHP(b) agency.)

Initial Organization

Working with local leaders in each area, NRMP assisted by inviting representatives from educational institutions, health institutions and professional groups to attend informational meetings. Some came out of curiosity, some out of protectiveness of their own interests, some because they heard money was available and perhaps some because they anticipated an opportunity to give their area a stronger voice in health manpower production in the state. Whatever the reason, most kept coming and were willing to join their local colleagues in developing a funding application in March 1972. Each CHEC formed a "governing council" of interested institutions in the area, as shown in Table 2.

Unlike many other grant processes, funding was almost "instant." A special national grant supplemented by NRMP developmental funds permitted funding of all CHEC projects within three months of application. Included were the two Medical Center "resource groups"—the Mayo Institutions and the University of Minnesota Health Sciences Center.

Coordination

The NRMP Central Office staff employed a number of techniques to spirit continued meetings of these new groups and to foster communication and cooperation. Emphasis on local responsibility and assistance to the local project director were

important keys. Field visits by NRMP staff assisted in "trouble shooting." Regular meetings of the nine project directors at NRMP offices provided accountability for each group, but also gave each a perspective of "the whole."

What Did CHEC's Accomplish?

The emphasis in the first year of CHEC activities was necessarily on planning and development. In fact, the funding award required this emphasis rather than starting activities, perhaps traditional ones, without first clarifying a need. Activities of the CHEC's will be described in five sections: Organization, Problem Solving, Major Activity, Continuance and Highlights.

Organization

Bringing the right mixture of educators, providers and public members together. Despite their common need in producing the right person for the right job, many of these key people had never met each other. Working together in a specific organizational setting with CHEC-type goals was without precedent in all seven of the geographic areas.

Problem Solving

The emphasis was on confronting local problems in health manpower education—new manpower, education for existing manpower and public education in health. The intent was to seek appropriate solutions, either within the area or by using other resources. This activity also acted as an organizational stabilizer because of its emphasis on local involvement with local problems.

Major Activity

Each of the seven Community-based groups embarked on some form of assessing local needs

in health manpower education. A common survey form was developed but modified for the local situation in all seven areas, either in format or technique of administration. Completion before July 31, 1973 was an original objective which will be met by each CHEC. The results will give each CHEC a base for planning educational programs. Hopefully, it will also help justify the costs of producing such programs.

Continuance

All of the CHEC's plan to continue operation and have survived the challenges common to young, untested organizations—of travel to meetings, often over great distances; of threat to independent action; of accountability to a responsible group; and of developing a sense of purpose beyond the rhetoric of the initial plan. The toughest challenge is yet to come, but all are enthusiastic about meeting it—to continue the organization with staff after the termination of NRMP funding on August 31, 1973.

Some Highlights

Organization and activities crossed over State boundaries—

Six counties in North Dakota are part of the Min-Dak CHEC. Programs have been developed in educational institutions in *each* State which will serve health personnel in *both* States.

The Northeastern Minnesota CHEC includes Northwestern Wisconsin counties and Superior State University of Wisconsin. It has developed a master plan for educational programs in the health occupations which will involve educational institutions and providers in both States.

Educational programs have resulted from improved communication of need between providers

and educators—

A training course for nurses aides is being developed by Moorhead Area Technical Institute for St. Ansgar Hospital, Moorhead.

A ward clerk training program at Mankato Vocational Technical Institute has been developed for the health care institutions in South Central Minnesota.

The Central Minnesota CHEC, as part of the University AHEC program, has developed several new educational programs for allied health personnel; an exchange program between hospitals for regional laboratory services; and two "Tele-lecture" series for nurses.

Moorhead State College (Minnesota) is developing a program to permit nurses in the Minnesota-North Dakota area to acquire credits toward a degree while continuing employment.

The Medical Centers have become "involved"—

Improved communication and cooperation between University of Minnesota Health Sciences Center and Mayo Institutions have resulted from this project and is readily acknowledged by both organizations.

Departments within the Medical Centers have become involved in the development of continuing education programs for use by the CHEC's.

The Centers (usually together) have had continuous contact with the seven Community-based groups, and intend to continue it.

University Health Sciences Center will produce a brochure which will list in one place for the first time and for general distribution to health professionals—a consolidated list of continuing education opportunities via the University of Minnesota.

Discussion and Summary

Are the CHEC's important to anyone but the relatively few who are involved in the projects?

What will happen to the interest level of those involved if the surveys and interpretations do not rationalize "more of same" in manpower production?

At the point of writing this article, the "jury is still out" on these and other questions. However, there is this evidence of CHEC's importance in the eyes of others:

1. A special task force for the State Comprehensive Health Planning Agency in a study independent of (but concurrent with) the first year of CHEC's, recommended that "regionally based consortia of educational institutions, providers and public members should be established to provide local accountability and to provide review and comment upon proposals for the new health manpower programs from that area." This recommendation did not get discussion in the 1973 Minnesota legislative session, but may receive later consideration.

The Higher Education Coordinating Commission of Minnesota, which reviews and recommends new programs and curricula for educational institutions, recently asked the Northwestern Minnesota CHEC for review and comment on two competitive proposals to establish a new nursing program in that area.

2. The CHP(b) agencies have recognized the importance of a constituent group like a CHEC giving special attention to the problems of health manpower education and training. Working relationships between the CHP(b) agency and the CHEC's have been compatible during the first year. The "separate but related" premise of the CHEC may be key and could be jeopardized by discontinuance of outside funding.
3. At least one test of viability and enthusiasm is the ability of a CHEC to find other sources of support. At this writing, six of the CHEC's have firm plans for continuation of staff after the termination of NRMP funding on August 31, 1973. The remaining three are optimistic about obtaining funding or other means of continuance by September 1st.

Profiles of Medical Practice

RUSSELL N. HILL, PH.D.,* WINSTON R. MILLER, M.D.†
and GEORGE M. CAMPBELL, M.A.‡

MANY FORCES are operating to change the practice of medicine. But there is a dearth of quantitative data. Current social imperatives to increase the quality and accessibility of health care services prompted this study of medical practice in Minnesota today. It endeavored to describe quantitative characteristics of the professional activities of practicing physicians, making comparisons by type of practice and by medical specialty.

The questionnaire survey methodology followed the pattern set by the Center for Health Services Research and Development of the AMA in "Periodic Survey of Physicians" studies conducted since 1965.¹ This investigation was more extensive than those carried out by the AMA.

In March, 1972, questionnaires were sent to all 3,711 Minnesota physicians classified by the AMA as 020—primary professional activity in direct-patient-care (physicians enrolled in graduate medical education were excluded). Of a total of 1,878 questionnaires returned by July, 1972 (51%), 373 were eliminated because of retirement, out-of-state migration, data deficiencies, or classification errors. After adjustments, the 1,505 respondents represented a 44% study sample of Minnesota's 3,383 direct-patient-care physicians. Response rates for subgroups by specialty varied from 18% for Radiologists to 68% for Pathologists, but most others approximated the overall average of 44%.

Many physicians did not answer all of the questions. In some cases it was stated, or could easily be inferred, that the items were not appropriate to his type of work; in others the lack of response can only be a matter of conjecture. A few answers were eliminated from analysis by the study team because they were inappropriate and

obviously due to a misunderstanding by the respondent. Although the 382 staff physicians classified as 020 at the Mayo Clinic participated in the study, many of the questions were omitted because they were not equally applicable to this institution. Mayo data, although not identified as such, are included in sections I, III, and X to XIV of this report.

Computer analysis displayed the number of physicians answering each question, the range of responses, the mean values, and the standard deviations from the mean; it also subdivided the data by type of practice and by specialty. Whenever possible, comparisons were made with national data from AMA profile studies.

General Work Characteristics

Overall averages of general work characteristics for the 1,505 physicians in the study group are shown in Table 1. Compared with 1970 national averages, Minnesota physicians worked 7% more hours and saw 9% more patients, but spent slightly fewer hours in direct patient care and worked about one week less per year. In-hospital work constituted only 35% of the average Minnesota physician's time. The 37% of responding physicians who indicated more than one specialty spent 27% of their time in the secondary specialty,

‡Research Associate at Northlands Regional Medical Program, Inc.

and the 8% who indicated a tertiary specialty devoted 13% time to that field. Additional tabulations indicated that the Minnesota physicians worked an average of 10.3 hours per day 5.34 days per week, spent 5.7 hours per day in the office, and devoted an average of 15 minutes per visit to the average of 24 visits per day.

Characteristics of Office Practice

Table 2 shows six groups of characteristics of the office practices of all physicians in the study group except Mayo physicians. It may be inferred from the data that 19% of office services were delegated to employed assistants since only 81% of patients were personally seen. Medical and pediatric-type patients occupied 63% of the physician's time, and 23% of time was spent on well-person examinations. Although only 12% of the Minnesota population is over 65, 28% of physicians' time was spent on this subgroup. The total number of laboratory, Xray, and EKG tests per week almost equaled the total number of visits, and three-fourths of all tests were completed in the physician's office. The remarkably large volume of these tests can be better appreciated by calculation of grand totals for the 737 responding physicians—nearly 90,000 tests per week, of which over 21,000 (23%) were sent out of the office. The average Minnesota physician conducted 5,735 tests per year in his office practice.

The 2.3 employees per physician fall into three subgroups—nurses 0.65, technicians 0.42 and secretary-receptionist-others 1.23. RN and LPN nurses were employed in approximately equal numbers. Compared to national averages, Minnesota physicians employed about one-third more assistants—the same number of nurses, twice as many technicians, and one-third more other employees.

Few physicians responded to a question concerning the need for additional employees. Only 85 employment opportunities were reported, including 18 specifically identified positions for specially trained nurse or ex-corpsman assistants.

Delegation to Staff Assistants

To define more precisely the kind of patient care work delegated to staff assistants, physicians were asked to estimate the degree of delegation (< 50%, > 50%, 100%, or none) for 16 office services. Table 3 shows mean percentages of phy-

sicians who delegate to *some* degree. Although 100% delegation was reported by some physicians for each kind of service, the only service with 100% delegation by a majority of physicians was accounts and billing. In addition, 37% reported 100% delegation for insurance and other forms, 22% for injections, 9% for routine dressings and taking off casts, and 3% for physicals on well

persons and taking routine histories.

The high rate of response to this section suggests a great deal of interest in this subject, and the numbers indicate that Minnesota physicians now delegate parts of their work to a significant degree. Differences between the principal specialties will be discussed in later sections.

Characteristics of Hospital Practice

Virtually all physicians in Minnesota hold hospital privileges, and those in this study group indicated that 35% of their time was spent in hospital work. Table 4 shows seven parameters of hospital practice.

A high degree of physician referral is reflected by the 712 responses (63% of sample) and the mean of 32% of referred patients. Thirty-one percent of the study group indicated they do deliveries; 36% that they do major surgery; 48% that they do minor surgery; and 37% that they do surgical assistance. On the average, physicians engaging in these services did significant numbers of procedures each year.

TABLE 4

a. Deliveries	345	59
b. Major Surgicals	407	118
c. Minor Surgicals	544	88
d. Surgical Assistance	419	43

Characteristics of Nursing Home Practice

The average nursing home case load for 748 respondents (67% of study group) was 17.1. GP-FP and IM physicians carried approximately equal individual case loads and 88% of the total calculated case load; GP-FP physicians alone carried 70% of the total case load. The frequency of nursing home visits varied widely among individual physicians from weekly to once every six months. The overall average was one visit every 8.8 weeks. Sixty-six percent of 518 respondents (46% of study group) indicated that they would delegate work to a Geriatric Nurse Practitioner if one was on duty in the nursing home.

Home, Nursing Home and After-Hours Visits

Questions concerning numbers of these visits per week elicited responses from 69 to 74% of the study group. There was an overall average of

12 visits per week—2.2 home visits, 4.8 nursing home visits, and 5.5 after-hours visits. Primary physicians made 72% of all reported visits, 60% of which were made by the GP-FP group alone. The latter group averaged three visits per working day.

Professional Fees, Income and Expenses

Table 5 shows overall average responses to specific inquiries concerning the economics of medical practice. Response rates varied from 40% for the dollar value of one unit of the Relative Value Index to 78% for using the RVI to some degree. Comparisons with AMA data showed that Minnesota minimum office and routine hospital visit fees (1971) were moderately less than the 1969 national averages but slightly higher than those for the West North Central geographic area. However, professional expenses were significantly higher: 28% higher than the national average and 16% higher than that for the West North Central area.

When the net income and expense items are divided by hours worked per year, Minnesota physicians in the study group averaged \$15.29 per hour (net) and an overhead of \$10.48 per hour.

9. West North Central Average Expenses*		23,431
10. West North Central Average Net Income*		41,288

*Most recent data available was for 1969¹.

Although only 19% of physicians reported following the Minnesota Relative Value Index completely, 63% used it to some degree. Third-party payors covered a large percentage of both hospital and office services. An overall average of 13% of all physician services were donated free or discounted for poor patients.

Comparisons by Type of Practice

Comparison of Solo practitioners, Partnerships, Groups, and Institutionally-based-physicians showed some significant differences. An obvious difference was a higher value for institutional-type services by institutional physicians. The most noteworthy differences which were observed related to the larger service loads carried by partnership physicians. Compared with overall averages, partnership physicians worked 2.6 more hours per week, 0.6 more weeks per year, and had 16% more office visits, 41% more home visits, 96% more nursing home visits, 13% more hospital admissions, and 11% higher net income. National data (1969-1970) on working time, patient visits, and income for partnership physicians are very close to the 1971 Minnesota data both grossly and relative to other types of practice.

The data for solo physicians are close to overall averages except that they worked about one more week per year and did 22% less laboratory, Xray, and EKG work in their offices. The number of tests sent out was about the same as that of other physicians. The smaller number of tests performed in the offices was matched by a correspondingly smaller number of tests per office visit.

The data for group physicians are similar to overall averages except that these physicians reported a little more time off, more delegation of work to assistants, moderately higher expenses, and slightly higher net incomes.

General Practice and Family Practice

Although this subgroup makes up only 26% of all physicians in Minnesota, it constitutes 32% of *patient-care* physicians and 37% of this study group. Because of the large size of the GP-FP group, average data were compared with averages for the combination of all *other* specialties, rather than the average for all physicians. Comparisons showed that GP-FP physicians worked 133 more hours per year (5%), had 61% more office visits per week, did 57% more laboratory, Xray, and

EKG tests per week, admitted 24% more patients to the hospital, carried a nursing home case load 1.5 times larger, made over twice as many home, nursing home, and after-hour visits per week, and employed 13% more office help.

Although GP-FP physicians made up only 37% of all physicians in the study group, they did more hospital admissions, deliveries, surgical assistance and nursing home care than their proportionate amounts. As shown in Table 6, the 67% of them who reported doing deliveries did 59% of all deliveries reported from the entire study group. The 39% who reported doing major surgery did 15% of all reported cases.

TABLE 6
GP-FP Services

	% of GP-FP's Answering Question	% of Total Reported Services by GP-FP's
Hospital Case Load	92	35
Hospital Admissions	80	47
Deliveries	67	59
Major Surgery	39	15
Minor Surgery	67	38
Surgical Assistance	65	63
Nursing Home Case Load	86	70

Reported charges by GP-FP physicians were 25% lower than the average of all *other* physicians for minimum office calls, routine hospital visits, and routine home visits. Professional expenses averaged 26% higher, gross income 7.5% lower, and net income 27% lower.

Compared to national averages for GP-FP physicians, average charges for minimum office calls were 2.4% lower; charges for routine hospital visits were 16% lower; professional expenses were 28% higher; and net income was 6.9% lower.

Internal Medicine

Internists made up 12.5% of all patient-care physicians and 12.9% of the study group. Although most Internists function as primary physicians, Table 7 shows that many items in the profile of practice differ significantly from the GP-FP group. Internists spent twice as much time per office visit, did 50% more tests per visit, spent more time with elderly patients and chronic illness, carried a heavier hospital case load, and delegated the same or more services to assistants except for telephone advice. Although Internists reported spending two-thirds of their time in their primary specialty (IM), over three-fourths of them reported spending an average of nearly one-third

of their time in a secondary specialty, and 13% of them spent 10% of their time in a tertiary specialty. That these activities constitute important aspects of the practice of Internal Medicine is evident by the reported one-third of hospital patients who were referred by other physicians.

Minimum office and hospital visit fees for Internists were 14% higher; and net income was 5% higher.

TABLE 7
Differences Between GP-FP & I.M. (Means)

	GP-FP	I.M.

% Chronic Illness	32%	46%
% Over Age 65	29%	38%
Hospital Case Load	10	18
% M.D. Referred	8%	33%
Out-of-Hosp. & Office Visits/Week	17	12
Delegation (% with some)		
Telephone Advice	63%	28%
Histories	43%	62%
Home Visits	19%	60%
Follow-up Visits	31%	63%

Pediatrics

Pediatricians made up 4.1% of all patient-care physicians and 3.8% of the study group. Profile analysis demonstrated the dominance of preventive care and episodic illness. Pediatricians reported the same large number of office visits per week as the GP-FP group, but more time was spent in well-person (36%) and acute episode care (43%) and less for hospital care (17%). Pediatricians employed the largest number of office assistants of any general specialty, but delegation of work was nearly the same as the GP-FP group. Although subspecialization was not as great as among Internists, nearly two-thirds of Pediatricians reported spending one-third of their time in a secondary specialty, and 8% reported spending another third of their time in a tertiary specialty.

Total hours of work and fee scales were comparable to Internists. Professional expenses were 9% higher than the average of all physicians, and net income was 8.5% lower.

Obstetrics-Gynecology

OB-G specialists constituted 5.6% of patient-care physicians and 4.3% of the study group. Emphasis on obstetrics was evident by the reported half of total working time spent on well-person

examinations and by the average of 157 deliveries per year. Thirty-five percent of the total number of reported deliveries were done by the OB-G group of physicians. In surgery, OB-G physicians reported over half as many total cases as General Surgeons (248 compared to 417). They reported the largest number of tests per office visit of any specialty (1.49). Total hours of work, fee scales, and professional expenses were similar to Internists and Pediatricians, but net income was higher than any other general specialty (\$46,821).

General Surgery

General Surgeons constituted 8.2% of all patient-care physicians and 6.9% of the study group. They worked more total hours per year than any other specialty group (9% above average) and spent over half of their time in hospital work. Fifty-nine percent of their patients were physician referred. They reported the smallest number of employed assistants and the lowest professional overhead of any general specialty. Routine visit fees were only slightly higher than the averages for all physicians, and reported net income was \$1200 less than that reported by OB-G physicians.

Other Specialties and Subspecialties

Twenty-two other specialties and subspecialties were included in the direct-patient-care classification. Collectively they constituted 38% of the total number of patient-care physicians and 44% of the study group. The relatively small number in each specialty made comparative analysis difficult. Overall averages of the profile data for these physicians were similar to the averages of all physicians except where the institutional base of many of them produced expected variations. Professional expenses were 18% less than the overall average, and net income was 18% higher.

Discussion

The research method followed in this investigation is basically a voluntary, subjective estimation of quantitative data by respondents to a mail-out questionnaire. Since there is no known method for validating the subjective responses, many persons, including some respondents in this study, have expressed considerable concern for inaccuracies in the method. However, where acquisition of objective data is not feasible, as in this study, subjective estimation by professionals is generally considered acceptable as an alternative

technique.

The results of this study correspond well, both grossly and relatively, with previous profile studies published by the AMA. Thus physician respondents throughout the country apparently respond similarly to this method of study.

Because of the unpredictability of response to mail-out questionnaires, the study-group used in this investigation was the entire population of direct-patient-care physicians. The 44% response was gratifying and is considered very significant, but the method does not permit any assumption that the characteristics of the non-respondent subgroup are the same as the respondent subgroup. In other words, the information obtained cannot be projected for the entire population of patient-care physicians.

The data presented offer potential assistance for tailoring educational programs to practice needs and for developing new incentive for correction of shortages. Many of the complexities of modern medical practice are evident; others can be readily inferred. Furthermore, the nature of future profile changes can be predicted if acceptance is given to the dictum that medicine is a service profession which responds to social demands for change. For example, delegation of professional services to assistants will undoubtedly increase fairly rapidly since it is already done to a significant degree.

This study focuses on quantities of services and therefore parallels the current social imperative to provide more services. Unfortunately, it was not feasible to investigate variations in complexity or quality of services. An office visit for a complex combination of diseases is very different from one for a common cold, but this study method could not reflect such differences.

This report constitutes a summary of the results

of the investigation. A comprehensive report is available for persons interested in more extensive data.

Summary

Broad profiles of medical practice were obtained from a mail-out questionnaire to all of the 3,383 direct-patient-care physicians in Minnesota. The 44% response demonstrated a high level of physician cooperation.

Compared with the data from national studies, Minnesota physicians averaged more hours of work, more patient visits, more office employees, higher overhead, and lower fees than the national averages. Net annual income was almost identical.

Delegation of office work was extensive for 16 different services. The Minnesota Relative Value Index was followed completely by 19% of responding physicians and used to some degree by 63%.

Physicians in partnership carried heavier practice loads than physicians in solo, group, or institutional practice. Minnesota data closely resembled national data.

The GP-FP specialty subgroup carried the largest quantitative load and provided the broadest range of most primary and many secondary medical services. It also had the highest expenses, but the lowest routine fees and the next to the lowest net income.

Profiles of the other general specialties demonstrated expected specialty characteristics and certain work advantages, but total work loads were similar to the GP-FP specialty.

Profiles of the 22 other specialties and subspecialties identified were not drawn because of the small number of physicians in each specialty and the extensive variation in work characteristics among individual physicians within each specialty.

Physician's Assistants for Minnesota Family Practitioners

NEVA WIESEKE GONZALEZ, M.D., M.P.H.*

FOR YEARS PHYSICIANS who wished to divest themselves of routine diagnostic and therapeutic procedures have individually schooled office nurses and assistants in carrying out some of these duties. Recently, formalization of this educational process has begun with the advent of new programs to train various types of physician support personnel: Physician's Assistant (P.A.), Physician's Associate (not to be confused with University of Minnesota medical students on preceptorships), Medex, Nurse Practitioner, Nurse Clinician, Child Health Associate, Orthopedic Assistant, Ophthalmic Technician, etc. The National Academy of Science categorized non-nurse physician's assistants into three types:¹ Type A assistants have a broad knowledge of medicine with enough depth to integrate common findings and share in the decision-making process; Type B assistants have knowledge in greater depth but limited to a specialty; Type C assistants are able to assist generalists but function at a more technical and superficial level than Type A assistants.

Most physician's assistant programs are patterned after one of the two early prototypes: the Physician's Assistant (now called Physician's Associate) program at Duke University,² or the Medex Program at the University of Washington.³ Duke's program was the first of all of the P.A. programs, beginning in 1965. Usual qualifications of entering students include two years of college and one year of clinical experience. Although initial students were all former military corpsmen, other qualified applicants have since been accepted. The program consists of 24 continuous months of courses: nine months of preclinical courses and fifteen months of clinical rotations, chiefly in the hospital setting.

The first Medex program was begun at the University of Washington Medical School in 1969. Only former medical corpsmen are admitted. The program consists of three months of formal training plus a year-long preceptorship with a physician who is committed to hiring the student after completion of the course.

The Duke approach is patterned after the medical school curriculum: a broad science background and a rather comprehensive review of all disease conditions, common and otherwise. In contrast, the Medex approach is task-oriented and provides no basic science background.

The impetus for development of a Physician's Assistant Program at St. Cloud State College (S.C.S.C.) came from the Student Health Service which was almost constantly besieged with patients presenting the repetitious and routine types of medical problems which could have been aptly managed by a qualified P.A. Although the administrators and academicians at S.C.S.C. did not provide the original stimulus, they were quick to lend their support. The program would help to fulfill the commitment of the Minnesota State College System to new directions in higher education: provision of new career opportunities to meet genuine needs of society; response to the challenge of new cooperative endeavors with the surrounding community; and integration of previous clinical and life experiences of the student into academic programs.

Early interest in developing a P.A. Program at S.C.S.C. occurred almost simultaneously with a movement to establish an Area Health Education Center (AHEC) in St. Cloud as recommended by the Carnegie Commission on Higher Education.⁴ The reaction of those most committed to the AHEC idea was that a P.A. Program at S.C.S.C. would fit well with any AHEC which might be established. As concepts developed, two

This project was sponsored by St. Cloud State College. It was a component of Northlands Regional Medical Program, Inc., supported by HEW grant #5 G03 RM-00021. Opinions presented do not constitute endorsement by NRMP, Inc. or the Department of Health, Education and Welfare.

*Director of the Allied Health Program, St. Cloud State College, St. Cloud, Minnesota.

types of "AHEC's" came into existence: a Community-based Health Education Center (CHEC), funded by the Regional Medical Program,⁵ and a University-based AHEC, funded by the Bureau of Health Manpower Education of NIH. Fortunately, the two groups are cooperating extremely well, with the local consortium providing much input concerning the desires and needs of the fourteen-county central Minnesota area. This P.A. program provides a prototype for development of other health manpower education programs to respond to local needs.

Activities carried out as part of the P.A. Program development contract (April 1, 1972-March 31, 1973) were directed toward two main objectives: (1) documentation of the need for and feasibility of a P.A. Program at S.C.S.C., and (2) planning the educational program.

In order to document feasibility, five areas of concern were studied:

(a) *Local physician support. Since no medical school faculty is available, area physicians must be willing to teach P.A. students as well as hire the graduates.*

(b) *Acceptance of the P.A. Program by other health professionals. P.A.s must work with nurses and other allied health personnel as members of the health care team. Also a successful local P.A. Program should recruit some of its students from these groups.*

(c) *Need for the P.A. Physician's Assistants is not really needed unless a significant proportion of the primary care duties of physicians is presently devoted to the types of routine tasks which can be delegated to assistants.*

(d) *Medico-legal problems related to the employment of the P.A. in Minnesota.*

(e) *Financial support for the educational program.*

Planning for the P.A. educational program was divided into three components:

(a) *Curriculum content. Should the broad-based Duke or the task-oriented Medex approach be used? Or is there a middle ground?*

(b) *The length of the educational program and the degree(s) to be offered.*

(c) *Admission policies and procedures.*

Feasibility studies

Physician Support

To determine the extent of physician support

for the program, a questionnaire was distributed to the 255 physicians who reside in the fourteen-county central Minnesota area. Ninety-three (36%) responded. The age and specialty distribution of respondents is shown in Table 1. Opinions of Area Physicians regarding the P.A. showed good receptivity (Table 2).

4. Willing to serve as Preceptor for P.A.		
Yes	59	32
No	9	30
Don't know	32	32
No answer	0	5

Although physicians outside of St. Cloud were mostly Family Practitioners and were somewhat older, their attitudes toward the proposed P.A.

program differed only in less willingness to serve as preceptors. A majority of all physicians felt a need for the program and were willing to consider hiring a P.A. The legal problem of lack of delegatory authority was the principal deterrence.

Over 70% of St. Cloud physicians preferred a Duke type or a four-year degree P.A. program, but also wanted to allow office personnel to take classes without working for a degree or certificate (Table 3). Nearly half of them expressed willingness to teach classes, and nearly 60% were willing to serve as preceptors.

Attitudes of Other Health Professionals

Another questionnaire was distributed to staffs of St. Cloud Hospital, St. Cloud Veteran's Hospital, and doctors' offices in St. Cloud. Since administrators distributed the questionnaires to hospital employees, the number distributed is not known precisely but approximately 900. About 50% (465) were returned. Contrary to rejection of the physician's assistant concept by organized nursing, 90% of nurse respondents felt that the P.A. would fill a need in health care delivery; 16% (76) were interested in becoming P.A.s themselves; and 56% (261) were interested in taking courses on a part-time basis while maintaining their present jobs.

Potential Office Work for Physician's Assistants

In an effort to document the need for P.A.'s,

diagnosis and time studies were carried out in the S.C.S.C. Student Health Service and in the offices of four general practitioners in the central Minnesota area. In the physician offices a tabulation was kept of office patients for a five-day week. Table 4 lists the most common medical problems encountered in the Health Service and in the private offices. In each case, the problems listed account for over 70% of all problems in each setting.

TABLE 4
Common Medical Problems in Office Practice

	Student Health Service %	Physician Offices %
1. Respiratory illness	27	11
2. Musculoskeletal problems	13	10
3. Procedures such as PAP smears and wart removal	6	19
4. GYN problems	25	3
5. Routine physical exams	—	16
6. Prenatal care	—	8
7. Cardiovascular problems	—	8

The differences in the kinds of medical problems seen at the Health Service as compared to those seen in the offices of private practitioners can probably be accounted for by: (1) the limited age range of Health Service patients, and (2) the fact that the Health Service study was done in January during a flu epidemic while the other studies were carried out in June.

The average time spent with each patient at the Health Service (four and a half minutes) was somewhat less than in the private offices (six minutes), probably because of the more routine nature of the students' complaints and the fact that Health Service nurses were already performing some of the duties of the P.A.

The Problem of Legal Delegation

The survey of physicians showed that the major deterrence to the employment of Physician's Assistants is the lack of clarity regarding legal status (See Table 2). The Minnesota State Medical Association introduced a delegatory amendment to the Medical Practices Act in the legislature in 1969, but no legislation resulted. Prior to the 1971 session, the State Comprehensive Health Planning Agency convened a committee of representatives of various health professions to recommend health manpower legislation. However, no agreement could be reached, and the committee disbanded. The Comprehensive Health Planning Council subsequently developed two companion bills: one gave general delegatory authority to

physicians; the other formed a Health Manpower Coordinating Committee to advise the State Board of Medical Examiners regarding the need for certification and to authorize experimental programs for new allied health personnel. Pharmacy, Nursing, and Optometry strongly opposed the delegatory bill; the State Medical Association opposed the bill to form a Health Manpower Coordinating Committee. The bills never got out of committee.

The Education Subcommittee of the Minnesota House Appropriations Committee charged the Comprehensive Health Planning Agency with responsibility for developing a bill which would be acceptable to the various professional groups. With regard to the Physician's Assistant, the committee recommended legislation patterned after that enacted in North Carolina: delegatory authority for physicians and placement of responsibility for regulation of Physician's Assistants with the State Board of Medical Examiners. No P.A. legislation was passed in the 1973 session, but a bill was passed to empower the State Board of Health to develop credentialing for new health professionals.

Prior to the 1973 legislative session, the Minnesota State Medical Association took the position that no additional delegatory legislation was needed or desirable. It was not needed because: (1) physicians already enjoy a general power of delegation under common, or decisional law; and (2) Physician's Assistants who are presently employed in the state have been able to obtain malpractice insurance at reasonable rates. It was deemed undesirable because: restricting amendments might limit full utilization of Physician Assistants, and such specific legislation might cause legal problems in utilization of currently employed assistants who are not graduates of a formal P.A. school.

Financial Support

The problem of funding unexpectedly became the largest obstacle to implementation. The 19:1 student-faculty ratio upon which the Minnesota legislature bases allocations to State Colleges was obviously not realistic for a program such as this.

The University of Minnesota requested supplemental federal funding for the P.A. Program at S.C.S.C. as a part of its AHEC program. This was not granted because, as a federal AHEC contract official explained, federal funds were available specifically for Physician Assistant pro-

grams. Federal funds had been available but were committed to existing programs; none were available for programs which were to be implemented in 1973.

The chancellor of the State College System requested supplementary funding for the program from the 1973 Minnesota legislature. The request was not granted.

The Faculty Allocation Review Board at S.C.S.C. recently allocated enough faculty positions to implement the program without the extra legislative funding. However, St. Cloud State College has chosen not to implement the Physician's Assistant Program as such until College officials have had more opportunity to discuss the matter with legislative leaders who will be instrumental in providing adequate long-range funding for the program.

Planning for the P.A. Educational Program

A Physician's Assistant Program Advisory Committee was formed to assist in program planning and to help guide the new program proposal through the many committees which must grant approval prior to implementation at a State College. The Advisory Committee was composed of representatives of various departments of the college, a community physician, and the college's Allied Health Director.

After examining the curricula of many P.A. programs, it was decided to incorporate certain aspects of both the Duke and Medex programs into S.C.S.C.'s program: it would provide students with a broad science base but would conform to the realities of primary care practice in clinical instructional content. No specialty tracks would be offered and clinical experience would be gained chiefly through preceptorships rather than through extended hospital rotations. Preliminary curricula have been completed for all course work.

The survey of St. Cloud physicians (Table 3) indicated preference for a four-year program. The committee felt that students who successfully passed a four-year program of this nature deserved a B.S. degree and that such a degree would be indicative of their level of competence. The program itself would be only two academic years in length but would follow two years of appropriate general college study. Because it was felt that some individuals who have had considerable patient care experience may have gained the equivalent of two years of college through non-degree training, self-study, and experience, it was decided

to permit such students to enter the program. These students would be awarded an associate of science degree upon successful completion of the course.

The following criteria would be used for selection of students: clinical experience, education, area of residence, personal attributes, American College Test scores, and commitment on the part of a physician to employ the applicant following graduation. A set of application forms and selection procedures were developed. The California Personality Inventory would be administered to applicants who pass the initial screening, both as a selection procedure and as a start toward gathering data to determine personality traits which are most desirable in a P.A.

The Physician's Assistant Educational Program was reviewed and approved by the following committees: S.C.S.C. Liberal Arts and Sciences School Curriculum Committee, the S.C.S.C. Curriculum Council, the S.C.S.C. Faculty Senate, the State College Board Curriculum Advisory Committee, the State College Board, the Higher Education Coordinating Commission's Advisory Committee, and the Higher Education Coordinating Commission.

The American Medical Association would provide two kinds of credentialing for Physician Assistants: (1) accreditation of educational programs for the primary care P.A., and (2) uniform nationwide certification examinations for individ-

uals who are not graduates of approved programs as well as for those who are.

Summary

Studies carried out in development of a Physician's Assistant Educational Program indicate a high degree of acceptance of the P.A. by physicians and other health professionals in central Minnesota.

Studies in the offices of Family Practitioners and a Student Health Service demonstrated that certain medical problems are seen repeatedly and most of these could be managed by an assistant.

No delegatory amendment has been passed as yet by the Minnesota Legislature; this still discourages many Minnesota physicians from employing a P.A. despite the evidences of increasingly secure legal status.

The college's willingness to support the program has provided encouragement. However, if the program is to be launched and sustained, a broad base of legislative support will have to be established in order to assure adequate fundings over a period of years.

The program is geared to helping to meet health care needs in the geographic area served by S.C.S.C. It would provide a solid base of knowledge in the sciences. Instruction in the clinical areas would concentrate on diagnosis and treatment of conditions commonly seen by primary care physicians in Minnesota.

Role and Preparation of the Adult/ Geriatric Nurse Associate

EVA ANDERSON, R.N., M.S.*, ELAINE COOLEY, R.N., M.S.†
and ALMA SPARROW, R.N., M.S., M.P.H.‡

IN AN ATTEMPT to satisfy the current increased demand for health care services, changing relationships between health care providers has been occurring. This has created a need for expanding and re-defining the roles of all health professionals. The change or metamorphosis of roles throughout the health care system has been of particular concern in the expanding role of the nurse. Development of the nurse to her fullest professional potential is seen as one way to increase effectiveness, efficiency, and quality of health care delivery.

Increased use of nurses in an expanded role began formally with the advent of the Pediatric Nurse Practitioner prepared initially at the University of Colorado.¹ Through such continuing education programs for nurses it is being demonstrated that physicians and nurses can establish a collaborative role relationship in the delivery of primary health care. The essential components to effect this role change are "lowering of attitudinal barriers, correction of educational deficiencies, and dealing with real and imaginary legal restriction of nursing practice."²

Many efforts have been made to promote expanded roles for nurses in adult and family health care. The Frontier Nursing Service was one of the first groups to report utilization of nurses in this manner. Other advocates of this role for nurses are Bates,³ Ford,¹ Kirk,⁴ Lysaught,⁵ and Scott.⁶ Many of their programs focused on spe-

cific clinical settings and were considered experimental, but several have evolved into continuous course offerings.

In support of the expanded role concept, the Department of Health, Education, and Welfare Secretary's Committee to Study Extended Roles for Nurses has developed and published a report detailing the extended scope of nursing.⁷ This was a first attempt at a formalized definition of the expanded nurse role.

The Adult and Geriatric Nurse Associate Program developed and piloted by the University of Minnesota, School of Public Health, Public Health Nursing Program, focuses on preparing nurses to function in an expanding role in the delivery of health care to the adult and geriatric population. In this expanding role the nurse assumes some clinical decision-making responsibility that has formerly been associated only with the physician. However, the new program maintains the professional nursing component—the teaching and counseling role, the family orientation to care, and a special concern with the psychosocial elements of health and disease.

The expanding role involves greater nursing responsibility along with significant primary care-taking responsibilities which are shared with the physician, including the physical and psychosocial health assessment. For the nurse this expanding role has aspects of what has been the traditional public health nursing role. The additional aspect is that the nurse is taught greater depth in physical assessment skills, thereby increasing the level of nursing responsibility and decision-making and increasing the degree and quality of nurse-doctor communication.

Objectives

In April, 1972, the Public Health Nursing faculty of the School of Public Health initiated the pilot project to develop and implement an educa-

This project was sponsored by the School of Public Health, University of Minnesota. It was a component of Northlands Regional Medical Program, Inc., supported by HEW grant #5 G03 RM-00021. ‡Director, Program in Public Health Nursing, School of Public Health, and Project Director, Adult and Geriatric Nurse Associate Program, University of Minnesota.

tional program to prepare Adult and Geriatric Nurse Associates. The overall purpose of the project was to expand the nursing role to provide increased preventive and health promotion services to the adult and geriatric population, with emphasis on service to rural areas where the need was greatest.

Specific objectives of the project were:

1. to develop and implement a curriculum to prepare nurse associates;
2. to offer this educational program at both urban and rural sites around the state, utilizing a traveling nurse faculty and local physicians;
3. to identify the dimensions of the nurse associate's role in delivering health care to the adult and geriatric population;
4. to develop a collaborative relationship with physicians in the delivery of care; and
5. to seek further economic support for program continuation based on evaluation of the pilot project.

Project Description

Several activities were carried out prior to the formal offering of the educational program. Interest in and potential utilization of the nurse practitioner were solicited from physicians, nurses, hospital administrators and consumers around the state through letters, personal interviews and public speaking engagements. Potential sites with student and physician commitment to the program were also sought during the summer of 1972. An Advisory Committee was formed with members representing nursing, medicine, public health, state legislature, senior citizen housing, hospital administration and nursing homes. This Committee served as an information channel to the professionals as well as to the consumer and provided direction for development of the educational program which would prepare nurses to meet identified needs in the community.

The educational program began on October 2, 1972. This continuing education, five-month, work-study program consisted of 110 hours of classroom instruction accompanied by 460 hours of clinical practice experience. Course content included interviewing techniques, medical history taking, physical examination skills, problem-oriented recording, pathophysiology review and problem identification based on the collected data. Also included was the nursing management of

acute minor illnesses and stabilized chronic illnesses. The major focus was placed on the recognition of the range of normal and on the identification of deviations from normal with translation of these findings into appropriate nursing action.

Classroom material was presented in a lecture-discussion format utilizing audio-visual aids as adjunct teaching tools. Video tapes were produced by the public health nursing faculty and physician specialists with the assistance of the audio-visual coordinator in the School of Public Health. In addition, physician, nurse and other health specialist lectures were audio-taped for classroom use. A few commercially prepared tapes and records were also employed.

Clinical practice experience was arranged and supervised by local physician-mentors. The clinical experience was obtained at the student's employment site. Additional clinical practice areas within the community were arranged for each student when necessary, to obtain a complete range of experience. Education at the employment site permitted involvement of the new role in the setting in which the student would be functioning as a Nurse Associate.

In an attempt to meet educational needs of professional nurses residing in rural areas, the program was designed to be offered at selected sites around the state. A traveling nurse faculty from the School of Public Health presented the didactic material at these employment sites on a bi-monthly schedule. Bringing the educational program out to the student in her community allowed more nurses around the state to participate in advanced educational pursuits and encouraged them to remain in practice in these rural sites. For the pilot project one rural and one urban site were selected. Three students were selected in the Thief River Falls area and six students in the St. Paul-Minneapolis area.

The nine students who participated in the pilot project were selected on the basis of maturity, problem solving ability, and evidence of independent decision-making in past work experience. These attributes were determined by use of a standardized psychological test (California Psychological Inventory) and personal interviews with the student and her employer. In addition, each student and her employer were asked to define a role within their health care agency for the student upon completion of the program. All employers

contracted with the School of Public Health to release the nurse-student from her job responsibilities for participation in the program.

A composite profile of the nurses enrolled in the pilot project was: married, female, 31 years of age, 1.5 children at home, a diploma preparation in nursing, and 8.7 years of previous work experience.

Current employment sites of the nursing students include a nursing home, hospital, public health nursing agency, group clinic, school of nursing, out-patient department of a county hospital, and solo physician's office. This variety of sites was deliberately sought by the faculty in order to assess the utilization of the nurse associate in a number of settings and positions, serving a consumer population with diverse characteristics.

Project Evaluation

Evaluation tools and methods for assessing the program objectives measured medical knowledge, task performance, and attitudes. An objective medical knowledge test was administered pre- and post-course. All students scored higher on the post-test than the pre-test, but the increase in score was not statistically significant. A pre- and post-task inventory analysis was also developed. The students rated the frequency with which they performed defined tasks, before and after the program. In addition, they were asked to indicate the ideal task performer from the health care team for each task. The performance of those tasks associated with history taking and physical examination increased in frequency, as expected. The performance frequency of tasks traditionally associated with nursing (i.e., patient teaching and counseling) remained constant, indicating that the nurses did not sacrifice the traditional components of nursing in order to add physical assessment skills. Rather, these skills have become an added dimension to their nursing role.

Student and physician-mentor evaluation of the entire project was elicited through written questionnaire and personal interviews. All regarded the course as informative and goal-oriented. The course length was generally considered satisfactory with appropriate allocation of time for classroom instruction and clinical practice experience. The program structure was considered very flexible in accommodating to student needs and abilities. Students felt they should be rotated through a variety of sites for clinical practice experience.

The physicians, however, favored student assignment to one site for the five-month period. Faculty analysis of student experiences demonstrated that clinical sites provided an appropriate case load for a variety of experiences in terms of patient age, presenting problem and diagnosed illnesses.

Students rated their own skills and knowledge in physical examination, history-taking, interviewing, management of minor illnesses and management of chronic problems. The majority of students felt they had a working knowledge and skill in all areas. Weakest areas identified by the students were the neurological and pelvic examinations.

Physician time spent with each nurse student varied during the course, with more hours of time initially and a gradual decrease in physician time as the student gained experience. Average weekly hours of physician time varied from three to 20 hours. Other variables were within the individuals themselves, nurse and physician, and their commitment to the project goals as well as their orientation to the educational process.

Consumer reaction to the nurse in this expanded role has been very favorable as assessed by both the physicians and students. Direct consumer reaction will be solicited by the project coordinators during this next year. Overall evaluation of the program was rated good with two physicians indicating "potential excellent."

Each student has begun to function as a nurse practitioner at her previous employment site. The different sites necessarily dictate differing utilization of the nurse based on that institution's needs. Defining the dimensions of the nurse practitioner's role in health care delivery has not been accomplished as yet. It is apparent that this role is still developing and more time is needed to allow for full and appropriate role experimentation. The public health nursing faculty will continue to monitor and record the nurse's utilization, her actions and performance, and both professional and consumer response to the nurse practitioner.

Because of the positive evaluations of the program and the increasing interest around the state from nurses and other health professionals, the School of Public Health sought state monies to offer the program on a continuing basis. An earmarked appropriation was awarded by the state legislature to fund this program for the next bi-

ennium. Plans include offering the program at other sites out-state where interest is keen, and doubling the number of programs offered by 1975.

Conclusion

The overall project goal of developing a course to prepare Adult and Geriatric Nurse Associates was realized. In addition, it was determined that such an educational program can be taught effectively away from the educational institution, thus allowing nurses in rural areas to participate. The impact of the Nurse Associate on the delivery of health care services to adult and geriatric patients is not measurable at this time, but isolated evidence has been accumulated indicating an increase in both quality and quantity of such care. Dimensions of the Nurse Associate's expanding role will be monitored over the next two years by documenting the activities and care delivered by the graduates of this pilot project.

Physician response to the program and to the Nurse Associate has been generally supportive and favorable.

Summary

The University of Minnesota, School of Public Health, Public Health Nursing Program developed a pilot educational program to prepare registered nurses to function as Adult and Geriatric Nurse Associates. The program was conducted at one rural and one urban site with nine nurses completing the course. The overall purpose of the program was to prepare nurses to function in an expanded role in delivering health care. Such role expansion for the nurse includes adding skills in data collection (history and physical examination) and problem identification thus permitting a higher level of decision-making in determining appropriate nursing intervention.

Statewide Policies for Planning Nursing Education in Minnesota

DONALD P. DRAINE, PH.D.* and ROBERT J. RUSTAD, M.A.P.A.†

IN 1973, THE MINNESOTA Higher Education Coordinating Commission (HECC) expects to complete planning for nursing education in Minnesota. The program will produce planning guidelines rather than directives in order to preserve autonomy of institutions and faculty initiative. After acceptance by the Commission, planning guidelines become statewide policy and official direction for educators to use in planning future nursing education programs. Recommendations will guide the legislature in program deliberations and constitute specific criteria for review and evaluation of new and existing educational programs by the HECC.

Consistent with creating statewide coordination in the voluntary mode, development of guidelines by the HECC relies on two resources: data and expertise.

In order to provide data on supply vs manpower requirements relative to the state's capacities to respond, projections are analyzed in three related areas:

1. the annual potential student pool for programs (based on expected choices to enroll and probable completion rates);
2. the statewide "design capacity" or potential annual output from all nursing programs (assuming full utilization of existing and future resources committed to nursing education); and
3. the projected annual manpower requirements based either on economic demand or on qualitatively determined need for services (including an accounting of the extant manpower supply and expected program output).

Expertise is employed by identifying the "players," organizing them into groups and charging

the groups to make advisory decisions. These decisions become statewide policy after acceptance by the HECC. The groups combine educators or producers of educated manpower and employers or users of educated manpower on the theory that each type has something to tell the other in educational planning. Together they can assist in data analysis and determination of implications for planning policies. The "players" are professional or lay persons who can commit the constituencies which they represent. When they agree their constituencies can be presumed to concur.

Background

In 1965 the Minnesota legislature established the HECC to conduct continuing study and planning for educational opportunities consistent with statewide needs and rational use of resources.¹ In 1971, the legislature mandated the Commission specifically to review and make recommendations about plans, proposals and priorities for new and existing educational programs in public post-secondary institutions. In 1973 authority for inclusion of private educational institutions was added.²

In 1965 the Minnesota Board of Nursing conducted a series of meetings with nursing organizations and public agencies to plan for nursing education in a comprehensive and coordinated manner. After several months the Board concluded that this group was not sufficiently broad to ensure effective planning.

In 1966, a *Citizens' Committee for Nursing* was created under sponsorship of the Minnesota League for Nursing and the Minnesota Nurses Association. In May 1970 this committee made a number of recommendations based on the *Upper Midwest Nursing Study*,³ concerning: (1) the supply of nurses, (2) financial support for nursing education, (3) accreditation, (4) faculty, (5) career mobility, (6) continuing education, (7)

*Assistant Executive Director for Academic Planning, Minnesota Higher Education Coordinating Commission, St. Paul, Minnesota.

†Research Associate with the Commission.

This project was sponsored by Minnesota Higher Education Coordinating Commission. It was a component of Northlands Regional Medical Program, Inc., supported by HEW grant #5 GO3 RM-00021. Opinions presented do not constitute endorsement by NRMP, Inc. or the Department of Health Education and Welfare.

nurse utilization and (8) community and regional nursing.⁴

Almost simultancously a *National Commission on Nursing and Nursing Education* published a series of recommendations on the future of nursing and added suggestions for implementation at the state level. A central recommendation in the summary report proposed that:

"Each state have, or create, a master planning committee that will take nursing education under its purview, such committees to include representatives of nursing, education, other health professions, and the public, to recommend specific guidelines, means for implementation, and deadlines to ensure that nursing education is positioned in the mainstream of American educational patterns."⁵

In response to that recommendation, representatives from the Minnesota Board of Nursing, Minnesota Nurses Association, Minnesota League for Nursing, Minnesota Licensed Practical Nurses Association and Northlands Regional Medical Program proposed that the HECC undertake a project to develop a statewide plan for nursing education.

The Nursing Education Project

The project goal was to design and test a statewide process which could produce and continually review a broadly acceptable and comprehensive plan for coordinated nursing education in Minnesota. The following specific objectives were included:

1. To prepare a data base for review and discussion of:
 - (a) the nursing student pool,
 - (b) the statewide design capacity in all levels of nursing education,
 - (c) the character, distribution and utilization of the nursing manpower pool, both present and projected;
2. To develop, through study and representative discussion, a comprehensive nursing education plan that will:
 - (a) determine the statewide need for nursing personnel of all kinds on a succession of target dates,
 - (b) take account of the need to implement previous state and national recommendations,
 - (c) plan an educational system that will provide needed personnel with specific recommendations to assure proper balance and distribution of nursing education programs,
 - (d) gear recommendations to produce prompt action and meaningful changes in nursing

education.

- (e) recommend sources of financial support for capital and operating expenses.
 - (f) maintain continued planning and evaluation of programs;
3. To design and appoint a broadly representative *Advisory Committee on Nursing Education* which will be engaged in the production of a comprehensive plan for recommendation to the HECC.
 4. To test this kind of planning process as a means of effective and acceptable planning for nursing education in Minnesota.

The membership of the *Advisory Committee on Nursing Education* was viewed as a key element of the project. Careful consideration was given both to the categories of membership and to the individuals appointed.

The 21 member *Advisory Committee on Nursing Education* provided representation from public and private institutions; from programs in universities, state colleges, junior colleges, area vocational-technical institutes, hospitals and private colleges; from programs for practical nursing, the three levels of registered nursing (Associate Degree, Diploma, Bachelor Degree), and graduate nursing; from users of nursepower including physicians and directors of nursing services; from the state student nurses association; and from all geographic areas of the state.

Eleven additional persons sat with the *Advisory Committee on Nursing Education* as consultants. They represented the State Board of Nursing, the Department of Public Welfare, the Department of Health, the State Comprehensive Health Planning Agency, the Minnesota League of Nursing, the Minnesota Nurses Association, the Minnesota Licensed Practical Nurses Association, the Minnesota Medical Association, the Minnesota Hospital Association, the Minnesota Association of Health Care Facilities, and the Northlands Regional Medical Program.

Regular members of the committee were responsible for evaluation of staff documents (research design, data analysis, etc.), review of the plan as it was developed and collaborative development of planning guidelines.

Special consultants provided liaison between the planning process and their respective agencies, and special technical assistance as needed.

The HECC staff was responsible for developing the research design; collection and analysis of data; acting as staff to the committee in clerical, professional and liaison functions; and producing the

final report.

The project was restricted to nursing and nursing education in Minnesota. It did not address the impact of policy decisions in Minnesota on non-resident students, the demand for Minnesota educated nurses in other states or the opportunity for Minnesotans to obtain nursing education in nearby boarder areas. While these were recognized as important issues, the limited available resources precluded consideration at this time.

In the absence of any agreed upon standards for defining "quality" or "need" for nursing care, or for behavioral parameters of nursing care, it seemed appropriate to limit the study to questions of supply and demand as economically determined.⁶

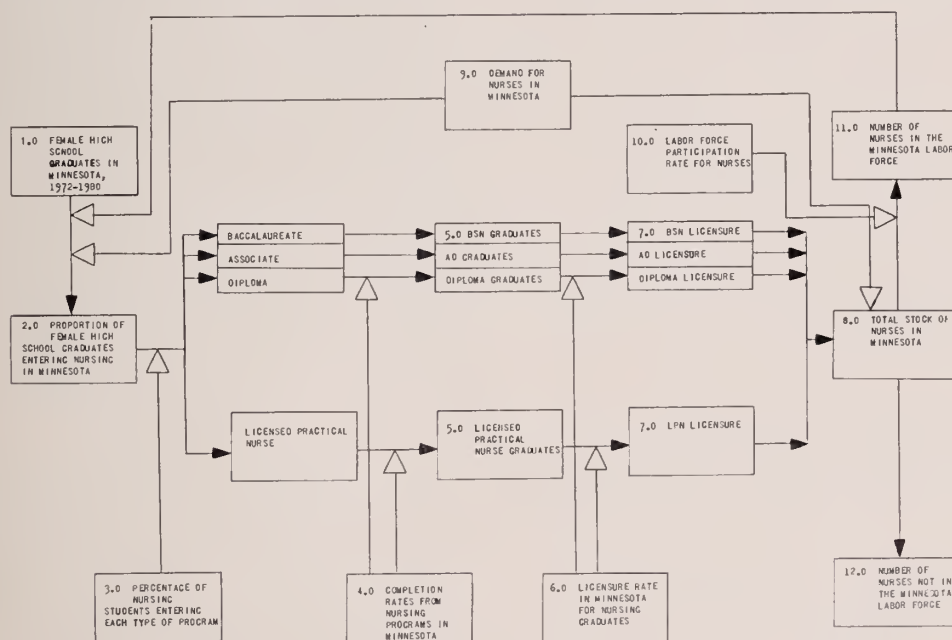

Methodology

The Figure graphically portrays the methodology for estimating the supply and demand for nurses in Minnesota.

Past experience was utilized to project developments to 1980. It was assumed that the output of nursing programs statewide is a function of economic demand for nurses,⁷ and that economic demand is determined by:

1. the demands for discretionary and non-discretionary care, and
2. the rise and fall in the supply of nurses.*

*Details concerning variables affecting nursing as an occupational choice are provided in Planning Report 12 of the Minnesota Higher Education Coordinating Commission (HECC).

Figure—Methodology for estimating the supply and demand of nurses in Minnesota.

In order to test this assumption, determinants were projected retrospectively to 1952 and annual estimates were compared with actual numbers of nurses for each year. There were no significant differences. With confidence, therefore, the same determinants were used to project the demand for nurses to 1980.

The demand also affects admissions and output of nursing education programs. In order to test this principle retrospectively the determinants were used to estimate the expected number of admissions, completions and licensures for each year since 1952. Estimates were then compared with actual through-put data available from the Board of Nursing. Again there were no significant differences. It was then possible to predict outputs of nursing programs to 1980 by use of projected population data from the Department of Health, and educational statistics from the Department of Education.⁸

Data from the Board of Nursing provided information needed to estimate the total nursepower pool in the state and the labor force participation rates. Finally, data were elicited on the number, location and capacity of all post-secondary nursing programs in Minnesota.

Findings

The *Advisory Committee on Nursing Education* accepted and discussed the following findings:

1. The demand for nurses in Minnesota between

1973 and 1980 is projected to increase by 19%, from 31,153 to 37,942. The increase will occur linearly and at the approximate annual rate of 2.5%.

2. The combined supply of RN's and LPN's is projected to increase by 24.6% if the low estimate occurs and 27.6% if the high estimate prevails, (38,675 and 39,789 respectively). In general, the percentage increase in the supply of RN's, LPN's and all nurses will decline slightly on an annual basis. The overall increase for RN's is 12.8% according to the low estimate and 15.3% under the high estimate. LPN's will experience a 51.6% total increase if the low estimate occurs and a 57.9% increase according to the high estimate.
3. The nursing manpower market is in an approximate state of equilibrium; that is, the supply and demand for nurses is relatively balanced.
4. The statewide demand for admission to LPN programs, should the low estimate occur, will not exceed the 1972 entry level admissions. If the high estimate is achieved, the 1972 entry level admission capacity will be exceeded by 2% to 5% by 1975. Beyond 1975 the high estimate will exceed the 1972 admission capacity by up to 12%.
5. The geographical distribution of LPN programs throughout the state has ensured reasonably good access for students in every planning region.
6. The statewide demand for admission to RN programs, as a category, will not exceed the 1972 entry level admission capacity. However, if hospital programs continue to phase out of operation, a shortage of entry level positions will occur before 1980.
7. Access to Bachelor Degree Nursing programs in Minnesota is restricted geographically.
8. The increasing demand for admission to Associate Degree Nursing programs will exceed the state entry level capacity by 1974.
9. Access to Associate Degree programs is restricted primarily to the metropolitan area.
10. If and when additional hospital Diploma programs in the Twin Cities are discontinued, the total number of entry level RN positions will fall below the 1972 level.

Policy Recommendations

The *Advisory Committee on Nursing Education* recommended several statewide policies for adoption by the HECC. In summary form they include:

- periodic reiteration of this planning process;
- involvement of statewide and regional health planning organizations;
- maintenance of the extant (1972) number of

entry-level positions in LPN and RN programs, subject to annual review;

- Commission encouragement of additions to the number of entry level positions as replacements when existing programs terminate;
- granting of preference to under-served regions of the state, either upon termination of existing programs or on absorption of surplus positions through increased student demand;
- involvement of the Board of Nursing in review of new programs insofar as curricula, faculty and clinical facilities are affected; and
- continuation of a statewide Advisory Committee on Nursing Education.

Next Steps

Once the recommendations have been adopted, they will serve as guidelines for institutional planners, the legislature, and the HECC in review of new and existing programs for nursing education.

The recommendations require certain actions for implementation: establishment and maintenance of working relations with the Board of Nursing and Comprehensive Health Planning Agencies; establishment of a continuing Advisory Committee; and periodic re-cycling of the planning process.

The *Advisory Committee on Nursing Education* recommended two additional studies. The purpose of one would be to determine behavioral differences between services performed by nurses educated in the several levels of nursing programs. The other would audit performance expectations among nurses trained at these levels. Objectives of these studies would include fixing criteria for arriving at acceptable service ratios between different levels of nursing education and planning for nursing education enrollments which are compatible with these ratios.

The committee also laid a foundation for addressing other pertinent issues such as career mobility, transfer of credits, continuing education, specialization, clinical station priorities, upgrading of programs, training of nurse-educators, interstate reciprocity, and improved communication.

Conclusion

The following basic objectives for nursing education were achieved: establishment and review of a data base; testing the acceptability and effectiveness of a planning process employing data and expertise; proving the effectiveness of a continuing *Advisory Committee on Nursing Education*; and developing a broadly acceptable, comprehen-

POLICIES FOR MINNESOTA NURSING EDUCATION

sive, statewide plan for nursing education.

These achievements can become routine in the

statewide voluntary coordination of post-secondary education in nursing.

Onward and Upward in Nursing

YVONNE HOFER SCHNARR, R.N., M.N.* and MARGUERITE HESSIAN, R.N., M.Ed.†

DAG HAMMARSKJOLD SAID, "As a climber you will have a wide sphere of activity even after, if that should happen, you reach your goal. You can, for instance, try to prevent others from becoming better qualified than yourself."¹ This statement has relevance today for the person who wishes to change educational and/or career goals. Such a person often finds resistance among those who control the manner in which "career mobility" might become a reality.

In nursing the bachelor's degree is becoming the baseline preparation for employment in community health, clinical specialties and administrative roles and has always been the required stepping stone for graduate study. However, many nurses are not prepared at the baccalaureate level. The purpose of this paper is to report on the challenge examinations in nursing developed at the College of St. Catherine, St. Paul, Minnesota. Challenge examinations are a means to facilitate career mobility, in this instance for corpsmen, practical nurses, and registered nurses who are graduates of associate degree and hospital-based diploma programs, toward a bachelor of arts degree with a major in nursing.

Career mobility is a popular bandwagon to be traveling on these days, but more easily discussed than accomplished. The problems are multiple for the individual wishing to change career goals and work toward a bachelor's degree in nursing:

1. Few institutions are willing to give college

credit for experience or previous education not obtained in their institutions.

2. Given the large number of students interested in the nursing major, standards and qualifications for admission have become more demanding. Many more qualified students than can be admitted to the nursing major are already enrolled in the colleges and universities.
3. Priority is usually given to those students who are already full-time in the institution.
4. Few institutions see the necessity of trying to absorb into their programs students with different backgrounds, philosophies and knowledge.

The student has the following options open to her.[‡]

1. She may enter as a college freshman and compete with the rank and file for admission to the major.
2. She may enter a college or university which will provide a special program whereby all the courses in the nursing major may be completed in one year.[#]
3. She may enter a flexible program with an open curriculum, allowing for self-paced learning.
4. She may enter a program where college credit and advanced standing are given through challenge examinations.

Within educational institutions, challenge examinations have been utilized far longer for general education courses than for the courses in the professional majors. In part challenge examinations emerged from the frustration of educators who were confronted with students from divergent institutions of learning and backgrounds. In the case of nursing, in order to give credit where credit was due, several Eastern colleges and universities, during the early 1960's, began offering challenge examinations to determine a student's theoretical as well as practical knowledge in relation to the nursing courses offered by the particular institution. This differed from the former policy of giving blanket credit to all who completed a prescribed course of study. A limitation of the blanket credit system was the failure to allow credit for previous experiential learnings. Al-

This project was sponsored by the College of St. Catherine. It was a component of Northlands Regional Medical Program, Inc., supported by HEW grant #5 G03 RM-00021. Opinions presented do not constitute endorsement by NRMP, Inc., or the Department of Health, Education and Welfare.

*Project Director for the Challenge Examinations in Nursing project at the College of St. Catherine, St. Paul, Minnesota.

†Chairman of the Department of Nursing and Associate Professor at the College of St. Catherine, St. Paul, Minnesota.

‡The female pronoun is used throughout this paper since most nurses are women.

#The University of Minnesota has a proposed program which would offer all of the nursing courses, including some challenge examinations to registered nurses allowing them to complete the requirements for a baccalaureate degree in two years or less. This proposal is awaiting legislative approval. A feasibility study was conducted under a grant from NRMP, Inc.

though challenge examinations may not provide a faculty with the same kind of information which would be collected over the period of time that a student was in the major, such examinations provide a means whereby a student may demonstrate the knowledge she possesses that is relevant to the major, whether she has gained her knowledge through formal education, incidental learnings and/or experience.

State college and university administrators in Minnesota, in response to their constituents, have encouraged their nursing departments to develop challenge examinations.² Private colleges also felt the need to respond to the requests of ever-increasing numbers of applicants wishing to enter the nursing major with advanced standing.

In the fall of 1970, faculty members in the nursing department at the College of St. Catherine began to consider the needs of the career mobilist. Thus began hours of discussion concerning the commitment of St. Catherine's to the student with advanced standing in the face of the already all-consuming efforts expended for the one with no previous nursing preparation. The faculty, hoping to cooperate with other interested nursing programs, initiated a statewide conference on career mobility for baccalaureate programs in nursing. This conference was subsequently sponsored by the Minnesota Board of Nursing and resulted in the formation of a Task Force on Career Mobility.

Administrators and faculty members at St. Catherine's supported the efforts of the nursing department to assist the career mobilist by permitting a departure in policy to allow eight courses* to be challenged rather than the usual two. For the past several years, the College Level Examination Program has been approved for students pursuing credit through examination for courses which fulfilled the general education requirements of the college and for some of the supporting courses for the nursing major. The hurdle still remained for the development of challenge examinations in the nursing major.

Project

Prior to receiving funds for the project, the faculty made decisions regarding the courses which could be challenged in the nursing major. The faculty decided that one course, "Theoretical Constructs in Nursing," could not be challenged

because of (1) the importance of the content to the practice of nursing, and (2) the length of time needed to integrate the philosophy of the course content and of the nursing program. For these same reasons, another decision was made that most courses could be challenged in their entirety, while in other courses, only a portion could be challenged.

The objectives of the project were threefold:

1. To construct challenge examinations in six of the seven nursing courses.
2. To develop a mechanism for making the test items available to other programs in nursing.
3. To communicate the results of the project to appropriate institutions and individuals.

Initially, members of the faculty met frequently to clarify their intents. From these discussions, a philosophy of career mobility was developed from which policy and procedure would follow.

Moving in, then, to the specifics of developing challenge examinations for which the college subsequently received funding, many questions arose. What is critical knowledge? What is mastery? How often will the examinations be given? How will they be graded? Several of these questions could be only partially answered initially. Discussion toward their resolution continued throughout the summer of 1972 when test items were developed, and into the current school year when the total nursing department faculty slowly continued to resolve the problems. Two areas needing further consideration are the delineation of mastery of content and the determination of critical knowledge.

Mastery refers to the acquisition of essential skills or knowledge at one's own pace regardless of the length of time it takes to "master" the content. A critical item is essential knowledge in the curriculum. A scheduled examination constitutes a time limit for acquisition of content knowledge. For example, a student may complete the mechanics of determining a patient's blood pressure correctly but fail to obtain an accurate reading. In mechanics she "passes," but because obtaining an accurate reading is a mastery skill, she may not progress in the course until she can perform the test repeatedly with accuracy.

As an example of a critical item, a student may take a practical test and pass all the items on physical skills, but may fail communication skill items in content on interpersonal relationships.

*There is a ten-course value to the seven nursing courses in the major.

Again on the average the student passes the test. However, her communication skills are still very poor. If this item is considered "critical," the student will not move into the next course; in fact this lack of knowledge may necessitate repetition of the course. Identification of "critical" skills is crucial since no further opportunity may present itself to evaluate these skills if the student successfully challenges subsequent nursing courses.

At St. Catherine's the testing of practical knowledge by simulation has been basic to the philosophy of the nursing department.³ However, the usual method involving time and effort by most of the nursing faculty had to be eliminated as impractical and too costly for challenge examinations.

During a ten-week summer period, the equivalent of five full-time faculty members worked on construction of test items. Following field trips, consultation, workshops and reading, a wide variety of audio and video tape items were developed to test the application of theory or practical skills. In addition to audio-visual methods, some simulated situations and a variety of paper and pencil items were developed to test other course content. These test items were reviewed by faculty members teaching in each of the courses in terms of basic construction of the item, content material being tested, and degree to which the item evaluated achievement of course objectives. Due to minor curriculum changes, oversights, and continuing evaluation of items by course instructors, additional items were added throughout the school year. All test items were filed on cards and categorized by course, content, and in some instances by course objective.

In order to establish validity and reliability, selected items were administered to junior and senior students currently enrolled in the nursing major at St. Catherine's. Item analysis was done by computer and each of the items was then re-evaluated.

Construction of challenge examinations also produced several indirect benefits:

1. Opportunity was provided to re-evaluate current course content, teaching and testing.
2. The faculty realized that the completed challenge examinations also benefitted all students in nursing.
3. The faculty became versed in necessary examination format for computerized grading and analysis.

The second and third objectives of the project required cooperation with other individuals and institutions. Two other projects, one sponsored by the University of Minnesota School of Nursing (funded by NRMP) and the other sponsored by the Minnesota Nurses Association (funded by the Division of Nursing, HEW), were closely coordinated with St. Catherine's. On several occasions all three project directors participated in programs at professional nurses' meetings to present the current efforts regarding career mobility in Minnesota.

In addition, all three project directors were actively involved on the Task Force for Career Mobility. This Task Force met repeatedly to categorize and classify the many test items. In addition to the items from St. Catherine's, contributions from five other baccalaureate programs became part of this test pool. All items were printed in book form, *Index of Test Items*, and copies were sent to the chairmen of the nine baccalaureate programs in Minnesota and to the National League for Nursing. The project directors also participated in planning and conducting career mobility workshops for faculty members from other nursing programs.

Discussion

The challenge examination project at St. Catherine's followed groundwork, planning and organization by the nursing faculty, several of whom were active in the Task Force for Career Mobility. The objectives and guidelines established by the Task Force were used as a basis for planning the project.

The project demonstrated that several courses in the nursing major could be organized into learning packets, thus providing flexibility and accelerated learning for career mobilists as well as generic students. In May and June of 1973, the nursing faculty developed complete learning packets for two nursing courses. Learning packets will present information in several modes, will arrange the information in order of priority of importance, and will contain pre- and post-tests to provide for self-evaluation. The use of video and audio tapes and other audio-visual materials as adjuncts will further enhance the use of learning packets.

Summary

Faculty in the Department of Nursing at the

ONWARD AND UPWARD IN NURSING

College of St. Catherine dealt with some of the problems faced by the career mobilist and developed challenge examinations to facilitate career mobility in a baccalaureate nursing program.

Through a variety of testing methods, the challenging student may receive college credit toward a baccalaureate degree in nursing.

A book, *Index of Test Items*, was prepared and

distributed to other schools and in the National League for Nursing.

Career mobility workshops for members of nursing faculties and presentations at state meetings disseminated the results of this project.

An apt motto for a faculty undertaking this process is, "Be favorable to bold beginnings."

The Relationship between Kisch's Health Status Proxy and Three Direct Measurements of Health Status

JOHN B. O'LEARY, M.D.,* HUSSEIN A. ZAKI, D.D.S., M.P.H., U.S.D.†
and JOHN F. ALEXANDER, PH.D.‡

THE PRIMARY PURPOSE of this study was to examine the interesting association between the disease conditions reported by a group of people and the health status of that same population. The stimulus for this work was provided early in 1971 when six small towns in Southwestern Minnesota formed a corporation to search for physicians and dentists who might be willing to come to their area. They submitted a grant request entitled "Joint Recruitment of Physicians" to the Northlands Regional Medical Program on August 1, 1971. At the same time, the Department of Family Practice and Community Health at the University of Minnesota initiated a survey of health care needs, wants and resources in the geographic area defined by the people of these six communities.

Despite its importance, health status is not generally well-defined. Even such universal things as cleanliness and healthy-appearing tissues have few scalar descriptions in the medical literature. Because of these problems, we chose only three well-standardized direct measures of health status; two dental and one quasi-medical: (1) The clean-

liness of the teeth, (2) The appearance of the gingival tissues, and (3) Physical fitness.

We also selected one indirect (i.e. proxy) measurement of health status¹ which has stimulated enough recent work^{2,3} to deserve the title well-standardized. These tools were used to investigate the relationship between health and disease which is the focus of our discussion.

Methods

The total population of household units in the six community area was identified through a cross-check of county directory, county atlas, telephone listings and school census. Each township was mapped and personal visits with knowledgeable individuals in each township were used to validate the household mappings. Random sampling within each age grouping was done using a random number table.

A stratified sample of 464 family units was chosen for the purpose of data collection. In August 1972, a team of interviewers explored health care needs, wants and resources as perceived by the person responsible for medical decisions within these households.[#] From this sample, a similarly stratified random subsample of 142 individuals, representative with respect to age, sex and number were chosen for the purpose of evaluating health status.

A general physical examination of each participant was carried out by one of the authors (JBO) with the assistance of two medical students.[§] Laboratory studies included electrocardiograms, blood chemistries and phytohemagglutinin determinations."

The total number of people completing the examination was 130. Three subjects were under five years of age. Their data was not included in the analysis.

*Associate Professor in the Department of Family Practice and Community Health at the University of Minnesota Medical School.

†Associate Professor in the Department of Periodontology at the University of Minnesota Dental School.

‡Professor and Chairman of the Department of Physical Education at the University of Minnesota.

This project was sponsored by the University of Minnesota Medical School. It was a component of Northlands Regional Medical Program, Inc., supported by HEW grant #5 GO3 RM-00021. Opinions presented do not constitute endorsement by NRMP, Inc. or the Department of Health, Education and Welfare.

#The household survey was carried out under the guidance of Ms. Anne Marie Reynolds and will be reported in more detail in a subsequent publication.

§The authors wish to express their appreciation to Mathias Masem and Philip Hoversten, students at the University of Minnesota Medical School.

"Studies of blood chemistries were carried out by Ms. Lois Jenkins under the direction of Dr. Robert Bridges of the University of Minnesota, Department of Laboratory Medicine. They are part of a survey of normal laboratory values to be reported. Studies of phytohemagglutinins were carried out by Ms. Ruth Cadwell and will be reported.

HEALTH STATUS

The dental examinations were performed for 10 subjects only. The remaining 20 subjects were either edentulous or didn't show up for the dental examination.

The oral hygiene status was assessed utilizing Green and Vermillion's Simplified Debris Index (DI-S).⁴ Six teeth were examined and the scale ranges from zero to three.

Periodontal disease was evaluated by the methods of Ramfjord's Periodontal Disease Index (PDI).⁵ Measurements were made on all surfaces of the same six specified teeth and the most unfavorable score was assigned to the tooth. Gingival color was noted as well as periodontal destruction and a score was assigned with respect to the Ramfjord Index on a scale of zero to six.

The physical fitness of the participants was measured by the body's ability to take in and utilize oxygen (Pred-MVO₂).⁶ Subjects were required to pedal a bicycle ergometer against a series of carefully calibrated work load increments. Observation of the pulse rate response to the work loads was utilized to predict maximal oxygen consumption. Because of the age differences in heart rate related to oxygen consumption during work, age correction factors are built into the prediction equation. There are no established age correction factors for children under 15 years of age.

The Kisch Health Status Proxy (HSCORE) was self administered following the procedure as originally described by Kisch et al.¹ This probably resulted in lower mean scores as Carlton and Miller² found an increase in total scores when the conditions were read aloud by an interviewer.

The Kisch Health Status Proxy, first reported by Kisch and Associates in 1969,¹ consists of four questions: Question 1 covers days of hospitalization, Question 2, the history of the use of medicines, Question 3 consists of a checklist of acute conditions—those which existed for less than a year, and Question 4 is a checklist of chronic conditions. Each condition is assigned a numerical weighting and the higher scores represent a tabulation of more conditions of greater severity.

Results

It proved impossible to rank order physical examinations in regard to health status. It was our subjective impression that we were examining a generally healthy rural population.

Mean DI-S scores by age and sex are presented in Table 1.

TABLE 1
Debris Index Simplified (DI-S) Mean Scores
by Age and Sex

Age Group	Females		Males		Both Sexes	
	n	Mean DI-S	n	Mean DI-S	n	Mean DI-S
5-9	10	1.79	8	1.96	18	1.87
10-19	9	1.59	16	1.77	25	1.70
20-29	4	1.11	4	1.83	8	1.47
30-39	10	1.20	9	1.20	19	1.20
40-49	7	1.21	7	1.16	14	1.19
50-59	13	1.18	8	1.30	21	1.22
60+	3	1.43	2	2.50	5	1.86
Total	56	1.37	54	1.58	110	1.48

Generally, debris scores decreased as age increased. The mean score for the entire group was 1.48 and was significantly higher for male subjects 1.58 than for female subjects 1.37 ($p \leq .05$ rank sum one sided test). This tends to agree with other data in the literature.^{7,8}

Figure 1 is a graphic representation of Table 1 and depicts less debris on the teeth of girls

Figure 1

and young women. This is the finding usually reported in the dental literature. It may correlate with earlier female awareness of the value of oral hygiene in increasing attractiveness.

Table 2 shows P.D.I. mean scores by age and sex. In all surveys in which severity has been

taken into consideration, periodontal disease has been found to progress steadily with age.^{9,10,11} In this study the mean PDI scores increased markedly with age for both males and females.

TABLE 2
Periodontal Disease Index (PDI) Mean Scores
by Age and Sex

Age Group	Females		Males		Both Sexes	
	n	Mean PDI	n	Mean PDI	n	Mean PDI
5-9	10	1.13	8	1.23	18	1.18
10-19	9	1.99	16	1.78	25	1.85
20-29	4	3.42	4	2.50	8	2.96
30-39	10	3.15	9	3.69	19	3.41
40-49	7	3.80	7	3.76	14	3.78
50-59	13	3.81	8	4.28	21	3.99
60+	3	4.61	2	4.50	5	4.57
Total	56	2.94	54	2.80	110	2.87

In practically all surveys conducted in the U.S., the periodontal conditions are found to be significantly better in females than in males.^{12,13} In this study there was less periodontal disease in males than females in four of the seven age groups. Although the mean PDI score for females, 2.94, was slightly higher than for males, 2.80, the difference was not significant ($P > .05$ rank sum one sided test).

Table 3 shows the mean maximal oxygen con-

TABLE 3
Predicted Maximal Oxygen Consumption
(Pred.-MVO₂)

Age Group	Females		Males		Total	
	n	Mean Pred.-MVO ₂ cc/KG/mn	n	Mean Pred.-MVO ₂ cc/KG/mn	n	Mean Pred.-MVO ₂ cc/KG/mn
5-9	4	55.69	3	75.87	7	64.34
10-19	10	45.28	16	56.89	26	52.43
20-29	4	40.39	5	47.40	9	44.28
30-39	12	37.31	10	38.21	22	37.72
40-49	8	29.70	8	31.51	16	30.61
50-59	11	30.11	9	34.47	20	32.07
60+	0	0	2	21.82	2	21.82
Total	49	37.83	53	44.58	102	41.34

sumption by age and sex as predicted by pulse rate. The mean scores of oxygen consumption decreased markedly with age for both sexes, as expected. The mean oxygen consumption in ml/kg body weight for the group was 41.34. Results of oxygen consumption by age groupings in this study tend to agree with those reported in the medical literature.^{14,15,16}

Acute and chronic scores for the Kisch Health Status Proxy did not differ appreciably so only mean HSCORES are tabulated. Figure 2 shows that females have higher HSCORES than males in five of seven age groups.

Figure 2

The mean HSCORES are presented in Table 4.

TABLE 4
Kisch Health Status Proxy
Mean Scores (HSCORE)
By Age and Sex

Age Group	Females		Males		Both Sexes	
	n	Mean H Score	n	Mean H-Score	n	Mean H-Score
5-9	12	9.75	9	15.22	21	12.10
10-19	11	9.45	16	15.50	27	13.04
20-29	4	28.50	5	8.60	9	17.44
30-39	13	10.92	11	9.00	24	10.04
40-49	8	25.63	8	18.63	16	22.13
50-59	14	16.36	10	12.30	24	14.67
60+	3	35.67	3	22.67	6	29.17
Total	65	15.66	62	13.98	127	14.84

HSCORES show no trend with age in males or females. The HSCORE for the entire group is 14.84. The females' mean score is higher than males, 15.66 compared to 13.98. This difference in mean scores is not significant ($P > .05$ rank sum one sided test).

An intercorrelation matrix for the five variables examined in the study is presented in Table 5.

TABLE 5
Rank Order Correlations Between the
Variables Examined

	Age	PDI	DI-S	Pred. MVO ₂
PDI	0.75†			
DI-S	-0.34	-0.19*		
Pred. MVO ₂	-0.66†	-0.44†	0.23	
HSCORE	0.18	.10	-0.05	-0.01

* $P < .05$

† $P \leq .01$

All of the correlations presented are calculated according to the Spearman's rank order correlation coefficient (Spearman's rho).¹⁷

Age was positively correlated with periodontal disease 0.75. This finding is consistent with previously reported studies. Age was negatively correlated with DI-S - 0.34 and predicted MVO₂ - 0.66. These three results are significant at the .01 level.

PDI scores were also negatively correlated with DI-S, -0.19 (significant at the .05 level). This finding should not be surprising because the amount of plaque present at one time is highly variable while periodontal destruction occurs over many years. Periodontal disease index was also negatively correlated with Pred. MVO₂ consumption 0.44 significant at the .01 level. This may suggest that the less physically fit subjects are also the subjects with the most periodontal disease, or conversely the physically fit subjects have less periodontal disease. All other correlations were not significant.

To further examine the relationship between physical fitness as measured by Pred. MVO₂ and periodontal disease, the sample was divided into four age groups and Spearman's rho was calculated for each group. The results are shown in Table 6. It is apparent that there is no correlation

TABLE 6
Rank Order Correlations between
Pred. MVO₂ and Periodontal Disease
within Age Groups

Age Group	n	RC	Level of Significance
5 ≤ 14	19	0.19	N.S.*
15 ≤ 30	21	0.01	N.S.*
31 ≤ 50	28	0.07	N.S.*
≥ 51	16	0.27	N.S.*

*N.S. = Not significant ($P > .05$)

between Pred. MVO₂ and PDI when subjects are classified by age.

The result of these studies (as summarized in Tables 5 and 6) shows that when the age is eliminated as a factor, there is no significant correlation between total health scores as measured by a standardized questionnaire HSCORE, and dental health as measured by oral hygiene (DI-S), the health of gingival tissues (PDI), and physical fitness as measured by the Astrand Bicycle Test.

Discussion

Definitions of disease and health are often ambiguous. For example, a widely accepted definition: "Health is a state of complete physical,

mental and social well-being and not merely the absence of disease and infirmity."¹⁸ This definition is typical of those found in medical literature¹⁹ in that it is vague. It is difficult to translate the subjective sense of well-being into an objective measurement.

Confusion arises when the words sickness, illness and disease are used in different ways. We will not debate the merits of any particular terminology but rather, will define the arguments more precisely, we have chosen Cassel's definition of disease.²⁰ To quote Cassel: "I shall use the word illness to mean what the patient has when he goes to the doctor's office and disease to mean what the patient has after leaving the doctor." In other words, we shall use disease to mean something which carries the physician's label; a name which can be accepted by both the physician and the patient. Figure 3 is a diagram of this definition. The ellipse represents those patients

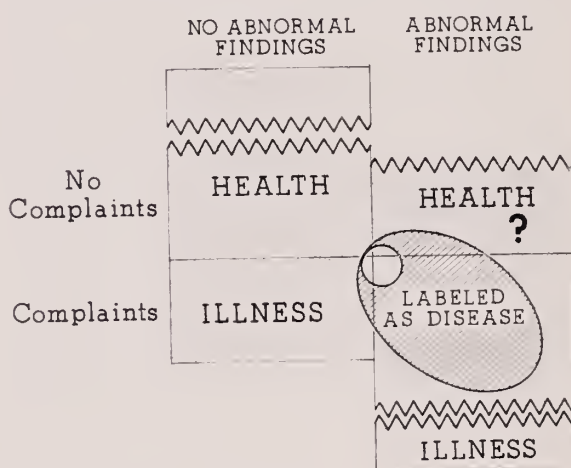

Figure 3

who have a disease; a condition with an acceptable name. The circle represents the margin of error. Those with complaints are, by definition, ill. Those patients with no complaints and no abnormal findings are healthy. The question mark is attached to those persons who have abnormal findings and no complaints. If they feel well are they healthy? Until the physician baptizes them with a disease label, they must remain in the large gray limbo of health.

Physicians take for granted that patients who have had various diseases are less healthy than other individuals. The concept that there must be a negative correlation between health and disease is a basic tenet of medicine. Despite this,

we are aware of the frequent counter examples; people who seemed frail and frequently ill and yet lived to an advanced age. These observations have given rise to many proverbs; for example, that the best way to live to a ripe old age is to get a chronic disease and learn how to take care of it, or that a squeaking gate hangs a long time.

The major lesson to be learned from the present study is that there was no significant correlation between the diseases reported by a group of people and three indices of health.

There are other recent studies which suggest that health and disease, as defined by the Kisch Health Status Proxy, do not consistently correlate. A study by Kisch and Kovner related HSCORE to the utilization of ambulatory services by subscribers to two different health insurance plans.³ The authors found that in 13 of 19 categories HSCORE did predict the level of utilization of health services, but that increasing intensity of illness did not correspond per se with increasing utilization of services.

Kessel and Shepherd²¹ studied the characteristics of people who were non-utilizers of ambulatory health services. They found that non-attendees had the same amount of recent trivial illness, but less emotional disturbance than recent attendees and that, in general, non-attendees took a favorable view of their own health status and considered themselves healthy.

Our failure to correlate disease conditions and health status measurements is not meant to suggest that no such correlation exists. The major

modifiers of health status, such as the automobile or subclinical arteriosclerosis, did not appear in the Kisch list of diseases. The present study serves as a reminder that too many of our tools are still primitive and measure the function of the organ rather than the man.

Summary

This is a report of the health status of a stratified random subsample (142 persons) of a rural population. It was done as part of a household survey of health care needs, wants and resources of an area including six small doctorless towns in which the people had formed a corporation to search for health care. Health status was measured directly by determining the extent of oral debris and periodontal disease. Bicycle ergometry was used to determine predicted maximal oxygen uptake as a measure of physical fitness. Rank order correlation of all variables considered in this population revealed no significant relationship between physiologic status, oral debris and periodontal disease when subjects were classified by age. There was also no significant correlation between these three direct health status measurements and a proxy measure of health status (Kisch et al.). The reasons for this apparent lack of correlation were discussed.

Acknowledgment

The authors wish to express appreciation to the people of Revere, Wanda, Wabasso, Lamberton, Jeffers, and Storden, Minnesota; to Dr. Wallace W. Nelson, the driving force behind the project; and to Dr. Winston R. Miller and Eugene V. Lenarz for their helpful reviews of this paper.

Indian Health in Minnesota

CHARLES McCREARY, M.D.,* CHARLES DEEGAN JR.† and DAVID THOMPSON, B.A.‡

MINNESOTA INDIANS ARE increasing in numbers and they are moving from the reservations to the Twin Cities. In 1960 the U.S. Census counted 15,495 Indians in Minnesota, 21% of whom lived in the metropolitan area. In 1970 there were 23,128 Indians counted in Minnesota, 45% of whom were in the metropolitan area. It is estimated that in 1973 there are 17,170 Indians in the metropolitan area and of these people, 10,130 live in Minneapolis.

Settling in the city, Indian people have encountered difficulties in health, education, housing, income, employment, law and justice. Some Indians have solved these problems by adopting to varying degrees the life style and values of the white community. The majority of Indians who have migrated into Minneapolis and St. Paul have not been absorbed into the white culture. They have preferred to maintain Indian identity, values and life style. This preference has meant exclusion from successful participation in employment, health care, education, and other aspects of white society.

For the past four or five years Indians in Minneapolis and St. Paul have been working to establish their own organizations to deal with their problems. These include Indian schools, Indian alcoholism programs, rehabilitation programs for Indians released from prison, establishment of Indian foster homes for children and many other similar activities. Underlying these activities is the principle of Indian control and operation of efforts to solve Indian problems.

In the field of health, the Indian Health Board of Minneapolis was established in 1971 with a

grant from the federal government to document the health care problems of Minneapolis Indians and to formulate proposals for solving these problems. An additional grant was made by the Northlands Regional Medical Program to study Indian health care in the entire state. The following report on health levels and health care problems of Minnesota Indians is part of this activity.

The report includes: (1) conventional health level indicators such as infant mortality rates, comparisons of age-specific death rates and causes of death, (2) information on health care and socio-economic conditions collected through a survey of Indian families in Minneapolis, (3) information about Indians who visited the emergency room of Hennepin County General Hospital and (4) statements made by Minnesota health professionals about Indians and statements made by Minnesota Indians about health professionals.

The information shows that Indian people suffer from poorer health levels than do white people, that Indian people do not use health services effectively, that Indian people live under difficult socio-economic conditions and that there is poor relationship between health professionals and Indians.

Conventional Health Level Indicators

The infant death rate[#] among Indians in the metropolitan area is higher than that of the white community. The Indian infant death rate for Hennepin County was 35.3 infant deaths per 1000 live births per year for 1968-1970. At Hennepin County General Hospital from 1967 through 1970 there were 615 Indian births and 23 infant deaths. The rate was 37.4 deaths per 1000 live births. The infant death rate for all races in Minneapolis for 1968-1970 was 22.9 infant deaths per 1000 live births per year.

Indian infant death rates are higher in the metropolitan area than on the reservations. In 1968-1970 the Indian infant death rate per year in Hennepin County was 35.3 and in Ramsey Coun-

It was a component of Northlands Regional Medical Program, Inc., supported by HEW grant #5 G03 RM-00021. Opinions presented do not constitute endorsement by NRMP, Inc. or the Department of Health, Education and Welfare.

[#]The Indian infant death rates used in this report are from a special matched study of birth and death certificates done by the Section of Health Statistics, Minnesota Department of Health.

ty 31.9. In contrast, the rates in two major reservation counties were 23.9 (Beltrami County) and 13.2 (Cass County).

Indian mothers do not receive prenatal care as early in pregnancy as do white mothers. Between 1967 and 1970 only 29.7% of Indian mothers in the metropolitan area began prenatal care during the first three months of pregnancy and 8.4% of Indian mothers received no prenatal care during their pregnancy. Among white mothers in Minnesota in 1969, 62.4% received prenatal care during the first three months of pregnancy and only 0.7% received no prenatal care during their pregnancy.

Indians die at earlier ages than do white people. In Minnesota in 1968-1969, 64% of Indian people who died were under age 65. In Minnesota in 1969 among all races, 31% of people who died were under age 65. The ratio of age-specific death rates for Indians compared with the age-specific death rates for whites in 1970 was as follows:

Age Group	Ratio of Indian/white
Under 5	1.66
5-9	0.42
10-14	1.58
15-19	3.32
20-24	5.31
25-29	3.88
30-34	4.67
35-39	4.02
40-44	4.18
45-49	3.49
50-54	2.58
55-59	1.69
60-64	1.44
65-69	1.05
70-74	1.20
75-79	0.74
80-84	0.78
85 and Over	.075

These ratios suggest that Indian people in contrast to white people are more likely to die between the ages of 10 and 74, particularly between the ages of 15 and 54.

Table 1 compares the major causes of death among Indians with those of all races. The data suggest that Indians are more likely than whites to die in young adulthood or middle age as a result of accidents. Indians tend not to live long enough to die of the diseases of aging (heart disease, cancer and cerebrovascular disease) which are the leading causes of death among whites. Indians tend to die during their productive years

whereas whites are more likely to remain alive until they have attained old age and retirement.

TABLE 1
Leading Causes of Death for Indians and for
All Races in Minnesota

Cause of Death	Indian 1968-1970 %	All Races 1970 %

Early Infancy	5.2	2.2
Diabetes Mellitus	4.6	1.8
Other Causes	21.0	17.0
	99.9	100.0

Information Collected through Interviews with Indian Families in Minneapolis

Since August 1972 staff members of the Indian Health Board have been in the process of interviewing all households in Minneapolis in which Indian people are known to live. As of June 1973 more than 700 households have been identified. The following is an analysis of the first 389 households which were interviewed between August 1972 and January 1973.

Socio-Economic Conditions

Two hundred fourteen (55%) of the households were one-parent families; 635 children lived in these households. One hundred five (27%) of the households were two-parent families; 332 children lived in these households. Seventy (18%) of the households consisted of single male or female households.

Fifty (12.9%) of the households received their primary source of income from employment, 215 (55.3%) received their primary income from Aid to Families with Dependent Children (AFDC), 17 (4.3%) from Social Security and Old Age Assistance, 10 (2.6%) from other sources, and 97 (24.9%) reported no source of income. (Those households reporting no income probably survive through help from relatives and food shelves, and by work at day labor pools.)

Money for Health Care and Utilization of Health Services

Thirty-five (9%) of the households had health insurance, 229 (58.9%) were on Medicaid, six (1.5%) on Medicare, three (0.8%) had other sources and 116 (29.8%) had no source of money for medical care.

Although approximately 70% of households had a source which would pay medical bills, only

2% of the households went to private physicians and 8.2% went to private dentists. One hundred nine (28%) of the households identified a hospital emergency room as their source of medical care and used this source only on an emergency basis. One hundred fifty-one (38.8%) of the households did not identify any source of primary medical or dental care.

Presence of Health Problems

At the time the Indian Health Board staff visited the households, they found someone who required immediate inpatient hospitalization in 45 (11.6%) of the households. In these 45 cases the Indian Health Board made immediate arrangements and admitted 18 people to Hennepin County General Hospital, four people to other public hospitals, and 23 people to private hospitals. Table 2 lists the types of health problems interviewers found in the 389 households.

TABLE 2
Health Problems Found in Interview Survey of
389 Minneapolis Indian Households

Households*	Type of Problem
No. %	
131 34	Dental Problem
54 14	Eye or Vision Problem
22 6	Hearing Problem
94 24	Preventive or Diagnostic Concerns
25 6	Mental Health Problem
37 10	Alcohol or Drug Problem
44 11	Chronic Disease and Disability
84 21	Acute Medical Problems
3 10	Other Problems
44 11	No Medical or Dental Problem

*More than one problem was found in many households.

Information Collected from Emergency Room Visits at Hennepin County General Hospital

During the first nine weeks of 1972 information was collected on 512 Indians who came to the Hennepin County General Hospital emergency room. The median age of the individuals was 28. These 512 people made 682 visits to the emergency room—an average of 1.3 visits per person during the nine weeks. The average number of Indian visits per day was 10.8 with the greatest number of visits on Saturday and Sunday. In 14.5% of the visits there was a notation on the chart that consumption of alcohol by the patient was apparent. In 9.4% of the visits the patient registered and left without waiting to see the doctor. It was estimated that at least 67% of the visits were for minor problems that could have been cared for in a private doctor's office or in a primary health care center rather than in

a hospital emergency room.

Of the 512 individuals 192 were in for care, 150 on Medicaid, eight on Medicare, and 34 on other public payment sources, 17 on part pay, 95 on full pay, 26 with private health insurance, and eight with source of payment not stated.

Who Is To Blame?

The health level of Indians is not good and the relationship of Indians to the health care system is not good. Who is to blame? The health care system? The Indians? Poverty? Poor housing? Bad nutrition? Lack of information about health? Alcoholism? The conflict between two irreconcilable cultures?

Both health professionals and Indians have expressed some negative attitudes about one another. It is worth cataloging these because they clarify important feelings which are real and which must be dealt with as a part of improving the situation. The following are comments which the authors have collected from health professionals and Indians during the past three years.

Negative attitudes health professionals have expressed about Indians:

"The Indians have become too dependent upon the federal government . . . They ought to quit drinking and get jobs . . . They ought to get up in the morning and go to bed at night . . . They don't come in for treatment until they're dying . . . They come for treatment in the middle of the night for problems which are not real emergencies . . . They bring their children in too often for minor problems . . . They neglect their children . . . They overutilize free health care . . . They don't follow instructions . . . They don't keep appointments . . . They don't say anything . . . When you talk to them they won't respond . . . Our first job as health workers is to teach these people to keep appointments . . . Medical care for Indians is the wrong approach, it's a band-aid approach. What they really need is to get a job . . . These people expect good treatment but they don't want to pay for it . . . They spend their money on color television. They should learn to save . . . They refuse to discipline their kids . . ."

Negative attitudes Indians have expressed about health professionals:

"They really don't care about Indians. They're just curious about us . . . They use us for teaching and experimentation . . . They make you wait for hours and then they don't even examine you . . . He came in with a broken jaw, almost ready to pass out, and they started hassling him for money . . . The nurse never stopped talking so I could not say anything. She told me I was a poor com-

municator . . . I'll die before I go back there . . . We're scared to bring our kids to the hospital for treatment. The last time they called child protection and tried to take the kids away from us . . . Both insurance companies were liable but the hospital turned me over to the collection agency. Ruined my credit rating. In court I thought I was talking to the judge but it turned out the guy I was talking to was from the collection agency . . . The Intern examined her and told us we spoiled our kids too much. She died at home of pneumonia . . . They had to close the hospital up there. I think the doctor had a drinking problem . . ."

What Should Minnesota Physicians Do?

Physicians cannot solve all Indian health problems by providing medical care. Indian health problems involve more than medical care and involve other forces beyond the scope of the doctor-patient relationship. Nonetheless, good medical care is one essential component that Indians must obtain in order to solve their health problems. As a minimal goal, Minnesota physicians should address themselves to the task of providing quality medical care in a dignified manner to Indians.

The following are some suggestions to individual physicians and to organized medicine in Minnesota:

1. Quit thinking about Indians and other low income people in stereotype forms. It's mentally lazy and can lead to errors in medical practice. The stereotypes are false. There is a tremendous diversity of life style, personality and socio-economic level among Minnesota Indians.
2. Be satisfied with doing the best you can with a medical problem. You may feel that medical care is only a short-term, band-aide approach to over-whelming social and economic prob-

lems. Remember that the Minnesota Indian community is a growing and healthy culture, hard at work on its social and economic problems, solving them in its own ways. What the Indians need from physicians is medical care, not socio-economic advice.

3. Be aware of the strong influence of white cultural values on physicians. Career-oriented planning, respect for the basic sciences as the basis of medical practice, keeping appointments, good financial management—these are cultural values that white health professionals generally accept and live by. Indian people would not give these values the same priority rating, and indeed might rate these values low. The danger to Indian people is that if they do not accept white values, they will not receive high quality and dignified treatment. Be careful that you do not hold your values in such a sacred manner that you become prejudicial against people who reject these values.
4. Support useful improvements in the health care system. For example, there should be a way for Indians (and non-Indians) to leave the welfare system and become lower middle income working people without losing the benefits of Medicaid. With the high cost of health care and health insurance, the loss of Medicaid is an incentive for people to stay on welfare. If Indians leave welfare and enter a low income job in which they cannot afford health insurance, and then suffer an expensive illness, they are forced into bankruptcy and back onto welfare.
5. Keep an eye on new medical services being developed by Indians. They will need to employ physicians either part-time or full-time. One contact for such service is the Indian Health Board of Minneapolis, 1925 Nicollet Avenue, Minneapolis, Minnesota 55403. Phone 332-7301.

Rural Satellite Health Facility

FRED T. NOBREGA, M.D.*; WILLIAM E. EVANS, M.D.*; PHILIP M. REILLY*;
EARL T. CARTER, M.D.* and GUY W. DAUGHERTY, M.D.*

THE RURAL TOWN without a doctor is of national concern. The National Advisory Commission on Health Manpower, aware of this has recommended that "specially organized ambulatory care centers be established especially in geographic areas of need such as urban slums, revitalized urban neighborhoods, new towns, and isolated rural areas."¹ This indicates the emphasis that has been placed on the extension of health care services into geographically deprived areas.

A rural town which has no doctor and which seeks a new physician or a replacement for a retiring doctor may, by implication, be considered deprived. Many of these towns, however, are situated in areas where residents may reach a regional medical center in nearly as little time as required for city residents.² It is therefore important to determine what local needs remain, what medical services are required, and what arrangements should be made by a large medical center to meet the rural community needs and requirements.³ It is equally important to determine how well satisfied the residents are by this form of practice, which includes the services of a physician's assistant, as opposed to that of the local general practitioner whom they have come to know and have accepted so well in the past.

In an effort to deal with this problem, the Mayo Clinic, Rochester, Minnesota, established a satellite health facility in a small nearby rural community—Plainview, Minnesota. In order to examine the effectiveness of this model in meeting local health care needs, the utilization of the facility, the change in local patterns of medical care, the services provided, and the referral practices and community attitudes toward health care were evaluated. A study was made of those residents who attended the facility. A special household survey

of the community after the facility's first six months of operation was also undertaken in order to assess the demographic characteristics of the population itself, its present and prior sources of medical care including hospitalization, the overall use of physician services in the community, and the general attitudes toward health care. Information from the survey was obtained by personal interview of a random sample of 20% of the households in the community. The age and sex distribution of those surveyed was quite similar to distribution of the population in the village and rural community from which the sample was taken.

In addition, the services of a physician's assistant in supplying a proportion of primary care services were explored and a variety of medical services was provided. These will be reported on subsequently.

Background

Plainview, Minnesota, is a trading center for a farming area. In 1970 the village population was 2,093; the immediate rural area, defined by the Plainview postal area, included an additional population of 1,487. The village, which is located 24 miles northeast of Rochester and about 20

Fig. 1—Map of Plainview and environs. G.P. represents general practitioner's office.

*Health Services Research, Mayo Clinic and Mayo Foundation, Rochester, Minnesota.

This project was sponsored by Mayo Clinic and Mayo Foundation. It was a component of Northlands Regional Medical Program, Inc., supported by HEW grant #5 GO3 RM-00021. Opinions presented do not constitute endorsement by NRMP, Inc., or the Department of Health, Education, and Welfare.

miles from small Mississippi River towns to the north and to the east of Plainview (Figure 1), has grown substantially during the last decade, partly by movement of retired farmers and their families to town and partly by the settling there of persons who commute to distant jobs.

In 1970, a delegation of civic leaders from Plainview petitioned the Mayo Clinic—the nearest large medical center—to find a replacement for its one doctor, who had discontinued his practice in town. Subsequently, a detailed plan designed jointly by groups from the medical center and local community representatives was developed for a one-year period of trial and demonstration.

Design of Health Facility

In the design of the demonstration facility, certain policies were established: (1) no restrictions were placed on age or place of residence; (2) a unit record system was maintained and records developed at the facility were incorporated in the files at the center; (3) patients with major trauma were referred directly to the emergency rooms at the affiliated Rochester hospitals; (4) any patient with a problem for which the facility was not equipped to handle and which was subacute was referred to a physician of the patient's choice, including the medical center; (5) fees were based upon customary levels of the medical center for similar services; and (6) extramural financial support was used for the evaluation only. The facility was open from 8:00 a.m. to 5:00 p.m., Monday through Friday. At other hours, during the evening and on weekends, the patients were advised to call the physician on duty.

Health Facility Personnel

The receptionist was responsible for obtaining demographic and clinical information on all patients seeking care at the facility and for recording data on prior sources of medical care and the reasons for seeking medical attention.

The physician's assistant—a graduate of Duke University Physician's Assistant Program with an additional two years' varied experience in the medical center—saw most of the patients. He took the medical history, proceeded with the physical examination, and managed the patient's problems according to the limitations defined by the physician. He quite frequently discussed the problem with the attending physician and was free to consult with any specialist at the medical center when he thought it necessary.

The physician attended the facility in the afternoons but was available to the physician's assistant in the morning by a direct telephone line between the health facility and the physician's office in the medical center. The physician followed the patients who had been seen initially by the physician's assistant as well as those patients whom he himself had seen first. Each physician from the group that planned the project attended the facility in turn, according to a monthly rotation schedule.

A pediatric nurse practitioner held a well-child clinic at the facility one morning each week. She had received intensive training from one of the medical center pediatricians and had two years' previous experience in this work.

Specialized diagnostic tests, when required, were performed at the medical center. Follow-up consultation was usually conducted at the health facility. Limited laboratory facilities, including those for routine blood counts, urinalysis, chest roentgenograms, and electrocardiograms, were available at the health facility in addition to those in laboratories at the medical center.

Findings of Study

Patient Characteristics and Utilization of Facility

One objective of the evaluation was to determine the characteristics of patients in terms of age, sex, education, residence, prior sources of care, and interval since the previous meeting between physician and patient. Utilization of the facility was also compared to that of other regional sources of medical care prior to or concurrent with the local opening of the facility.⁴

During the first year of study (September 1971 to the end of August 1972) the total number of registration visits for separate episodes of care (which may include several visits for the same problem) was 2,396; this total included 1,240 from the village, 484 from rural Plainview, and 672 from outside the Plainview area.

Individual patients coming to the health facility generally came from close environs (Figure 2). Of the individual patients seen in the facility ($N = 1,670$), 48% came from the village and an additional 21% lived in rural Plainview; the rest lived in nearby townships but only 4% of the patients lived more than 25 miles away.

Age Distribution

One of the distinctive features about patients

RURAL SATELLITE HEALTH FACILITY

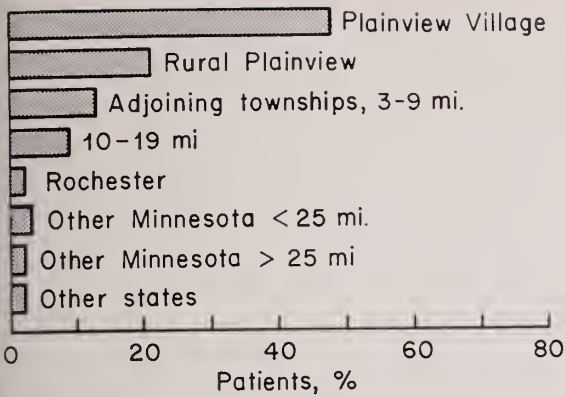

Fig. 2—Individual patients at health facility by place of residence (N = 1,670).

seen at the health facility was their distribution by age. The median age of the patients of Plainview village seen at the facility was 24, as compared to a median age of 33 years among the village population (according to 1970 US census); rural Plainview patients had a median age of 23, as compared to a median age of approximately 20 years for the general rural population.

Based on the proportion of patients' visits by age, it can be seen that younger patients from the village used the facility more frequently than would be expected from their numbers in the population (Figure 3). The frequency of expected age-specific visits to physicians was calculated on the basis of 1969 national health survey figures and the 1970 Plainview census.⁵ The expected proportion of physician-visits for patients age 24 or younger was 32%, as compared to the observed percentage of 52% among users of the facility. Whether this trend represents the special unfilled need of the young or the sign of conservatism of the elders in seeking newer opportunities for primary care remains uncertain.

Of the registrants at the facility, 57% were women compared to the 52% of women in the population (Figure 4). Furthermore, 45% of the

Fig. 3—Percentage ratios of observed to expected visits of patients to health facility among Plainview village residents, by age.

women seen at the facility were 25 years of age, as compared to 36% of women in this age group in the population. Among those seen at the health facility, 61% were under 25 years of age as compared to 42% of the population in the village population. The health facility was attended by young patients of both sexes, especially men. Among registrants older than 25, however, there were greater numbers of women in each age group.

Fig. 4—Comparison of patient visits and population from Plainview village, by age and sex.

Educational Level

Another measure of the type of patient using the local health facility is obtained from classifications, by educational level, of the heads of households. According to a recent study, in the United States "race and educational levels are more strongly associated with utilization [of physician services] than is family income."⁶ In this regard, the educational levels, as indicated by the household survey in Plainview, corresponded almost identically to the 1970 US census for the village.

The educational level of the household-head was higher for those who used the facility than among those who did not (Figure 5). Among

Fig. 5—Comparison of educational level (duration of education) of heads of households in Plainview village for users and non-users of health facility.

those who used the facility, the proportion of household-heads reporting 13 or more years' education was 31%, as compared to 14% not using the facility. This finding obtains even after the data are age-adjusted for differences among users and nonusers.

Level of income was not included in the survey.

Changes in Sources of Primary Medical Care

A series of comparisons was made to trace the pattern of medical care resulting from the introduction of this limited health facility in the community.

Records at the medical center of all patients from Plainview indicate that more than one-half of the population had received medical care at the medical center at least once during the prior six years. These records also verified that during the six months prior to the opening of the local facility, only 490 persons (14% of the total village and rural population) had received any medical service at the medical center. These rates showed that many persons used the medical center on a selective basis rather than for day-to-day care before the start of the local health facility.

By the end of the first six months of the facility's operation, 720 persons (20% of the Plainview village and rural population) had attended the local facility; only 224 persons (6% of the Plainview population) had come directly to the medical center without attending the local facility first. Although there was a decrease in the proportion of patients coming directly to the medical center for care (from 14% to 6%), there was an overall increase in the number of Plainview patients who sought care either at the local facility or the medical center (944 persons, or 26%). A large proportion of the services provided were preventive and reflected the type of primary care services delivered. A detailed analysis of the type and number of services and the contribution by the physician's assistant and the physician to the provision of those services is now being prepared.

In addition to the 224 persons coming directly to the medical center without attending the local facility, 148 patients were referred to specialists at the medical center, having first been seen at the Plainview facility; of these, 105 were Plainview village residents.

Analysis of Unmet Needs

Among health facility patients who were residents of Plainview village, 9% indicated that they

had previously been under the care of a doctor who was no longer present in the local Plainview community. This may be one indication of patients' needs and demands for the local facility.

Another measure of the amount of unmet demands was an analysis of the interval since the last physician-visit to village patients who used the facility initially. It was found that 40% of the village patients first seeking care at the facility had previously visited a physician within less than six months. While the National Health Survey data for 1969 may not be directly comparable, for populations outside SMSA the survey shows 53% seeing a physician within six months.⁷ Among Plainview patients the lowest physician attendance had been for those patients in age groups over 25 years. For example, only 30% of patients at the health facility between 25 and 44 years of age had seen the physician in the prior six months, and similarly 39% of patients between the ages of 45 and 64. Though perhaps not entirely comparable, the figures for these age groups from the national survey were 54% for ages 25 to 44 and 54% for ages 45 to 64 respectively. This suggests that adult patients first using the health facility may previously have had somewhat less care from physicians than might have been expected. After the initial six-month period of operation of the facility, the Plainview survey showed that 49% of the village population had reported seeing a physician within the previous six months.

Change in Community-Wide Pattern of Medical Care

An important consideration in assessing the patterns of medical care in the community is the change that occurred after the establishment of

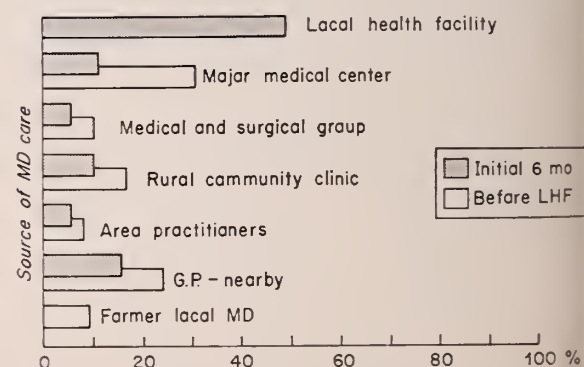

Fig. 6—Comparison of sources of physician care for Plainview village before and after institution of health facility.

the local facility.

For the period prior to the local facility, the pattern for use for each source of care (Figure 6) was reconstructed from the two sources of information on prior patterns of sources of care in the community. The first component is based on information from users regarding their prior sources of medical care, as stated on the first visit to the health facility. The second component is based on information from non-users obtained from the household survey. These two elements are combined to show the distribution of village residents by source of care before and after the establishment of the Plainview Health Facility.

Analysis of this summary shows that 49% of the patients chose the new Plainview Health Facility. This is the largest change in the overall pattern. The higher demand on the facility resulted in a lower demand upon other sources of care outside of town. While 31% of the village patients had previously gone to the major medical center, direct flow to this medical center declined to 12%. This proportion does not include the 48 patients seen initially at the local facility who were referred to the center for additional specialty services.

The study of initial change in patterns of care provides a basis for further assessment of the medical needs and medical services to a rural community as well as a base line for future trends in the source of care.

Discussion

This study reflects the experience of a large medical center in providing a limited facility for primary medical care to residents of a rural town without a doctor. The selection of the particular community of Plainview, MN, was related to the strong interest by leaders of the village in seeking local medical care and the medical center's determination to investigate its role in providing more basic medical needs to rural communities. The data obtained in the first year's experience of the health facility showed substantial support for the health facility by the residents of Plainview; while the facility offered a relatively limited number of medical services, this demonstration project did provide a measure of the perceived need above this specific threshold. The difficulty, as recognized by earlier researchers in the health care field, is that the "traditional method of projecting such issues—from present use patterns has the

serious drawback that if a service does not exist you cannot project it."⁸

The profile of patients who attended the facility was somewhat different from that of the population from which the patients came. For example, the users of the facility included a disproportionate number of children and young adults. This finding may be explained in part by convenience of the facility in terms of distance, time, and transportation required as well as by the reluctance of older people to change established patterns. Furthermore, the presence of a pediatric nurse-practitioner was in part responsible for the disproportionate number of children seen at the facility. One finding of special interest is that the patients coming to the health facility generally came from areas close by. Approximately one of every two residents of the community who were expected to seek medical care during the six-month period came to the facility, as compared to perhaps one of four residents of rural Plainview who sought such care during that period.

The heads of households of patients seen at the facility had a relatively high educational level. Since another study⁶ has also shown that educational level is more definitely associated with utilization of physician's services than is family income, this consideration may have special importance in the projection of future health care needs in rural areas.

For the most part, Plainview residents had not, however, been using the medical center for their day-to-day medical care. With the development of the health facility, an increased number of residents began to enter the larger medical system for routine primary care. As an example, one out of three health facility patients had no prior contact with the medical center system until their first visit to the local facility.

The rural community seemed to gain more convenient access to medical care at the center through this health facility, and it is possible that referral for secondary and tertiary care was more selective than had been the case previously. The need of some patients for medical care was more acute since their former doctor had departed from town; others had deferred seeing a doctor for an extended period of time. Children, young adults, and women especially showed a need for local medical care.

The community as well as the medical staff

benefited by gaining an experience with new health care techniques. Hopefully, this experience can

serve as a basis for the improvement of health care delivery in rural areas.

Mobile Unit Health Care in Rural Minnesota

LILJA A. SNYDER, P.H.N.* and GERALD L. SETTER, M.S.†

PROFESSIONAL NURSES have unique skills and knowledge which, if properly applied, can be used to fill some of the currently unmet health care needs of our people. Using these skills, they have the capability of: conducting assessments of health, including the lack thereof; counseling persons with health problems; providing health education directed at preventing, or at least detecting early signs of illness; and following medical direction for administration of many types of treatment for illness. In essence, nurses have a major role if we are concerned about *health care*.

The purpose of this report is to describe the 12 months of operation of a Mobile Health Care Unit, staffed by registered nurses. Since the Polk County Mobile Health Care Project constituted a new demonstration program for improved rural health care, this report describes five chronological phases of this activity: (1) Planning and funding, (2) acquisition of equipment, (3) pre-operational development, (4) operation, and (5) evaluation and cost analysis.

Planning and Funding

Rural counties in Northwestern Minnesota have common problems related to health care: (1) they have higher than state average age groups of the very young and the elderly; (2) the location of medical care facilities is usually centered in the county seat, and public transportation is either non-existent, or very limited; (3) they have a number of villages and towns where no form of health care is available, e.g. Polk County has 18 such towns and villages; (4) most of the physician population is middle age or older and the area does not seem to attract young physicians; (5) residents report that they are re-

luctant to bother physicians about minor problems because "doctors are so busy" and (6) there is no reason to believe that conditions will improve in the near future.

Literature reviewed gives conflicting views on the value of mobile units. Many of the mobile units described were designed to screen only one or two facets of a person's health and therefore were not comparable to the present project. The findings of the Subcommittee on Health of the Elderly reported: "There is a great need for additional efforts to prevent chronic disease on a national scale. Multiphasic screening shows great promise as a practical method for early detection of chronic disease . . . and could result in considerable time saving for physicians—an important consideration in the face of a severe and growing medical manpower shortage."¹ A report prepared by Northlands Regional Medical Program stated, "Area A (N.W. Minnesota) data forecast serious problems for the health care system in the near future. The supply and demand principle has been increasingly ineffective in rural areas such as Planning Area A."²

For as long as the agency has been in existence, the Polk County Nursing Service has been involved in early detection and prevention of illness. The trend for many years was to focus on the school age child, and apparently efforts have been successful. Communicable disease for which immunization is available is rarely encountered; few new tuberculin reactors are detected in testing programs; and parents respond well to recommendations made by the Public Health Nurse regarding further vision, hearing, dental, or medical evaluation. Mass screening programs such as Vision and Hearing Clinics for pre-school children, and Coronary Screening Clinics for men are well attended. Polk County people, given the opportunity, are prevention and early detection oriented.

A dovetailing of the obvious need for improved health care with the skills and experience of the

*Director, Polk County Nursing Service, Crookston, Minnesota.

†Was Health Services Coordinator and Health Economist at NRMP and is now employed at Minnesota Systems Research, Inc.

This project was sponsored by the Polk County Nursing Service. It was a component of Northlands Regional Medical Program, Inc., supported by HEW Grant #5 GO3 RM-00021. Opinions presented do not constitute endorsement by NRMP, Inc. or the Department of Health, Education, and Welfare.

agency seemed appropriate. "Wouldn't it be possible to staff a Mobile Health Unit with registered nurses and send it out to doctorless towns and villages on a regular basis for the purpose of providing *health* care to all ages?" This question, accompanied by an outline of the types of services nurses could provide, was posed to members of the medical profession in Polk County. Two primary goals were achieved: approval by the medical profession to try to find funding for the project; and appointment of a Medical Advisory Committee to help develop and provide medical support for the program. Next, approval was requested and received from the Polk County Nursing Advisory Committee and from the Polk County Board of Commissioners.

Exploring sources for funding became a long and arduous task. Only negative response was forthcoming in spite of great time and effort expended in making numerous inquiries. A suggestion from a local physician that contact should be made with Northlands Regional Medical Program proved to be the "pay off." The interest of staff was not only a pleasant change, but it reinforced the belief that the concept had merit. With the help of Northlands staff and the Medical Advisory Committee, a grant application was submitted in December of 1970. A number of setbacks occurred during the quest for funding, but suffice it to say that funds were awarded late in 1971.

Acquisition of Equipment

Although a detailed budget had been prepared for the grant application, now that financing was available, line items on paper had to become real. Which motorhome within the price range would serve this purpose? Will it be possible to recruit capable nurses who are daring enough to break with the traditional role to staff this Pilot Project? Who offers the best price on equipment? Many decisions were required. With the help of the County Engineer, a 27-foot Travco Motorhome was chosen as the vehicle. Floor plans called for two offices separated by a reception area which included a bathroom and storage for office supplies. Interior fittings would, for the most part, be done locally since factory modification would be more expensive. After consultation with various experts, orders were placed for necessary equipment.

Pre-Operational Development

After the vehicle and equipment had been ordered, the next priority was recruitment of staff. Consideration was given to experience, attitudes, and ability to relate to and have empathy for people. Two local registered nurses who more than met expectations were added to agency staff on January 1, 1972. Both indicated plans to remain permanently in this community. This is very important since agency acceptance is increased greatly by low staff turnover. The nurses spent two and a half months in orientation, which included: becoming familiar with resources in the area; orientation to agency policies; learning screening procedures to be offered on the Unit; spending a training period first with an internist and then with a pediatrician to increase skills in health assessment; and assembling a library of educational materials.

Although communities had indicated a need for this type of service, and had been alerted to the fact that funding had been obtained, no actual involvement had been requested until this time. At this point, each community was asked to provide two contributions to the program: first, to choose a community liaison aide, and, second, to indicate where it would be best to park the Mobile Unit during visits. Whether the community aide would be a volunteer or a paid employee was the responsibility of the community. When a community aide roster had been compiled, Mobile Unit nurses visited each one to explain aide duties. These included making appointments for the next visit of the Mobile Unit, providing community liaison and obtaining transportation and other assistance for patients when needed.

Meetings were held with the Medical Advisory Committee to set up policies for operation. Types of services to be offered and standards for referral were determined. Copies of medical policies were sent to all practicing physicians in the county, and suggestions and recommendations were invited.

Finally, the public was oriented to the advent of this new health care facility. The mass media was utilized, brochures were distributed liberally throughout the county, and talks were presented to lay groups describing the objectives and services to be available. Orientation of the potential patient population emphasized that the Mobile Unit was in the business of *health* care, not *sick* care, and was staffed by nurses, not doctors. After the

vehicle was obtained, modified and equipped, the staff took the Unit to each scheduled stop so that residents could view it and learn what services it would offer.

Operation

On April 3, 1972, the Polk County Mobile Health Unit began formal operation with regularly scheduled visits every three weeks to 18 communities. The following health care services are provided:

A. Early detection through screening. Nursing assessment of personal health status using the following screening techniques:

1. Review of history form filled out by patient—this becomes part of a health status interview and includes a family profile.
2. Measurement of height, weight, blood pressure, intraocular pressure, and apical and radial pulses.
3. Vision screening (Titmus machine) and hearing screening (Vasque for preschool age, Maico Pureton for others).
4. Tuberculin test (when indicated).
5. Denver developmental test for children six years and under.
6. Demonstration of breast exam, with return demonstration by patient.
7. Observation.
8. Urine screening (Bililabstix).
9. Determination of hemoglobin.

B. Prevention:

1. Review of immunization status of all ages. Immunizations are given when indicated by medical policies.
2. Prevention through health education—examples:
 - a. Teaching patients with diagnosed conditions how to become involved in self care. Diabetics are taught importance of diet management, exercise, foot care, urine testing, etc. Cardiacs on medications such as anti-hypertensives and diuretics are taught the purpose of the medication, the importance of taking it as prescribed, and the potential side effects to be avoided. Multiple drugs are reviewed to prevent harmful interaction.
 - b. Teaching men, particularly those with family history of heart disease, about risk factors and how to reduce them.
 - c. Teaching women the importance of periodic Pap smears and pelvic exams for early detection of cancer.
 - d. Teaching mothers of young children safety measures related to poison prevention.
 - e. Referring socio-economic problems to proper resources, thereby reducing stress factors relating to health status.

- f. Teaching health hazards which were revealed by the family profile.
- g. Direct instruction of proper nutrition versus food and vitamin deficiency where no disease condition yet exists; supplemental teaching where a special diet has been prescribed.
- h. Teaching proper body mechanics and environmental safety factors for health maintenance and accident prevention.
- i. Mothers are encouraged to visit physicians for pediatric well child exams; and adults for regular medical check-ups.

C. Health counseling:

Nurses on the Mobile Unit provide a resource for the "worried well." Patients who have minor conditions which concern them, but which they feel are not serious enough to "bother the doctor" seek direction from the nurse. The nurse is instrumental in motivating the patient to seek medical care when it seems warranted. On the other hand, she provides reassurance when that is all that is needed.

D. Treatment or service by physician request:

Upon physician request, nurses give injections, change dressings, remove sutures, and collect blood and urine samples to bring to the lab. Hypertensives under medical treatment are referred to the Mobile Unit for follow-up between clinic visits. A mobile phone on the Unit facilitates immediate contact with the physician.

E. Public education:

Articles concerning family planning, immunization, glaucoma and hypertensive screening are prepared for the mass media, alerting the public to the value of prevention and early detection. The public is invited to the Unit for screening and counseling.

Evaluation and Cost Analysis

Despite the fact that the Mobile Unit is a new approach in health care for Polk County, public acceptance has been very good. From April, 1972 through March 31, 1973 the first year of operation—the results were:

Total patients visits	2438
No. self referred	2137
No. physician referred	99
No. return by Unit request	202
No. first visits to Unit	1805
No. later visits	633
No. given health screening	1803
No. positive findings	908
No. given health counseling	1468
No. immunizations given	1004
No. tuberculin tests given	884
No. Unit referred to M.D.	666
No. Unit referred to other resources	157

In rural areas, population is sparse and numbers

alone are not too meaningful. Percentage of population in a village who have visited the Unit gives a better picture of utilization. This varied from 15% to 76%, and averaged about 38%. Utilization was affected by factors such as: distance to nearest medical center, mobility of residents, and percentage of elderly in the community.

Although no study has been done on utilization by age, it appears that the major portion of patient clientele was among the very young and the elderly. Recently there seemed to be an increase in the middle age group.

Feedback from the communities has been excellent. Patients are pleased with the service and report their satisfaction not only to the agency but to County Commissioners and physicians.

The "Nursing Assessment of Health Status" component of mobile health unit services resulted in detection and referral of 330 medical problems during the four-month period of December, 1972 to March 31, 1973. Itemization of referrals of positive findings is as follows:

Elevated blood pressure	72
EENT problems	45
Vision deficiencies	26
Hearing deficiencies	30
Suspicious lesions	17
Dermatological problems	7
CV or peripheral vascular problems	10
Gastro-intestinal symptoms	11
Genito-urinary symptoms	21
Endocrine disorder symptoms	3
Diabetic symptoms	5
Low hemoglobin	6
Pap smears	16
Medical check-up needed	32
Miscellaneous conditions	29

No satisfactory method for feedback from physicians has been found, although several methods have been tried. Confirmation of findings and appropriate medical treatment came from the patients themselves—not an ideal method of evaluation. Physicians on the Medical Advisory Committee have been most supportive, perhaps because they are closest to the operation. Some initial resistance and questioning of the nurses' role was experienced. This seems to have been replaced with increased interest on the part of some physicians and token acceptance by others. The Polk County Nursing Service has worked well with physicians in the past, and there is no reason to doubt that this relationship will continue.

In the interest of conserving staff time and preventing disruption of school routine, the Mobile

Unit is being used to conduct Mantoux screening and Immunization Clinics at many schools. The Unit is driven up to the front door of the school, and the children visit the Unit for their "shots." The Unit has also been used to give tuberculin tests to Nursing Home staff thereby helping them to conform to regulations with the least effort and expense. Children in one Head Start program received their immunizations from Unit staff, and nursing assessments were given to children who had not had a medical check-up.

Since the Pilot Project was designed for a three-year period, evaluation of performance after only one year of operation is tentative at best. The project approach concerns itself with health care, not sick care, and the health system is presently not geared to pay for this service. There is no doubt of its value in the minds of those who are directly involved in the operation. Many other avenues of use are presently being explored: expansion of service into surrounding counties; use by the migrant population who spend eight summer weeks in the area; use by industries where presently no health exams are provided; preschool and camp assessments which tax the physician's already full schedule; and expansion to other Head Start programs and other schools.

Cost Analysis

It was originally intended that this three-year pilot demonstration project would be continued by fee-for-service and local subsidy if it proved to be successful. Cost analysis was conducted to provide an understanding of developmental costs and an appraisal of support needed for continuation.

The costs of planning the project, preparing and submitting applications for grant support and other activities connected with obtaining funding cannot be exactly documented. It is estimated that the Polk County Nursing Service expended about \$1000 in time, effort and office services for these purposes.

Acquisition of equipment and pre-operational development required seven months of time and effort. Total costs were as follows:

Personnel	\$ 5,915
Purchase & Equipment of Mobile Unit	21,345
Garage & Insurance	647
Travel, Phone and Maintenance	198
Office Overhead	701
TOTAL	\$28,806
Total Operational Costs for the first year of	

MOBILE UNIT HEALTH CARE

actual operation were as follows:

A. Fixed Costs	
Personnel	\$26,400
Equipment	
Garage & Ins.	780
Travel, Phone & Maintenance	2,184
Office Overhead	996
B. Variable Costs	
Supplies & Long-distance	
Phone Charges	1,800
TOTAL	\$32,160

The project grant from NRMP provided \$29,08, and total fees-for-service amounted to \$2,61. In the first year of operation patient visits to the Mobile Unit totaled 2438. The actual cost per visit was therefore \$13.19.

In projecting expected costs per visit after the pilot demonstration period is completed several additional factors must be taken into account: (1) vehicle depreciation and repair costs should be included; (2) variable costs will increase proportional to increase in the numbers of patient visits; (3) the average nurse time per visit will probably decrease; (4) a maximum number of patient visits will be reached.

If the life of the vehicle is estimated at 10 years, the depreciation allowance is \$2,135 per year. It was estimated that repairs will amount to \$5000 during the 10-year life expectancy (\$500 per year). The variable costs in the first year of operation amounted to 74¢ per visit. Nurse visits were of two types—health assessment requiring one hour per visit and brief episode requiring 15 minutes per visit. The proportion of all visits which were health assessment visits decreased from 90% in the first months to 60% in the last month. It can be estimated that the proportion will eventually stabilize at 50%. On this basis the average nurse time per visit would be 38 minutes. Experience during the first year has shown that the two nurses spend 200 hours per month in actual patient services. Thus the maximum potential for patient visits will be 3,789 visits per year. Estimated total costs per year based on the above principles are as follows:

A. Fixed Costs	
Personnel	\$26,400
Equipment	
Garage & Ins.	780
Travel, Phone & Maintenance	2,184
Depreciation	2,135
Mechanical Repairs	500
Office Overhead	996
B. Variable Costs	
Supplies & Long-distance	
Phone Charges	2,804
TOTAL	\$35,799

Based on these principles and calculations, the average cost per visit at maximum utilization will be \$9.45. If a 10% salary increase for personnel is added, the cost per visit would rise to \$10.14.

These costs per visit appear quite reasonable when compared to the average cost of \$13.53 per home nursing visit by the Polk County Nursing Service and the average charge of \$12.20 for a physician home visit in Minnesota.³ However, the method of payment for this kind of health care services has not yet been established. Part can be collected as a fee-for-service, but part will probably require subsidization from public or private sources.

Several factors provide additional justification for this service program including its cost per visit: if screening detects a condition before serious illness occurs, then money has been saved; if a disease has been prevented, then money has been saved; if the patient did not have to make a 100-mile round trip and lose several hours of work, then money has been saved; and if *health care* is considered important, then this money has been well spent.

Summary

A Mobile Health Care Unit, staffed by registered nurses, visits 18 doctorless towns and villages in Polk County on a regular basis. Its major thrusts are health maintenance, prevention of illness and early detection of disease using screening, counseling, and education techniques. Its major concern is *health* care, not *sick* care. Although it is still in the pilot phase, public acceptance has been excellent and physician acceptance adequate.

A "Super-Nurse" for A Doctorless Town

MARETTA J. MUXLOW, B.S., R.N., P.H.N.*

THIS PILOT PROJECT asked the question—can a small mining community in Northern Minnesota resolve many of its health care needs by having a competent nurse working in a clinic setting?

Many rural communities in Minnesota are without a resident physician and face the likelihood of never being able to obtain one. Tower-Soudan, and the surrounding area of the Vermillion Indian Reservation have a population of 1,400-1,500 persons with a tremendous influx of tourists during the summer season which almost triples this figure. This is a community without physicians and is 25-30 miles from medical care and hospitals.

Surrounding communities are well staffed with physicians who also serve residents in Tower and Soudan. Seven general practitioners serve the Ely area through two clinics and a 47 bed hospital. One general practitioner serves the Babbitt area. Two physicians had been in Cook working with a 23 bed hospital. Virginia (30 miles distant) has two large medical center-type clinics with many specialists and several independent practitioners. The Virginia Hospital has a 173 bed capacity.

Demographic data show a wide age span in the population of this area. Since the closing of the iron mines, many residents have remained and retired here, perhaps accounting for the 18 to 20% of the population who are over 65 (state average is 11%). Situated on the south shore of Lake Vermillion, the sixth largest of Minnesota's 10,000 lakes, Tower-Soudan attract many young and middle aged adults owning businesses

relating to sports and recreational activities (e.g., resorts, marinas, snowmobile and motorcycle shops, etc.) The children of this age group comprise the school age population of 29%.

Since other studies have shown that up to 70% of patient-physician visits do not really require diagnostic and management skills possessed by doctors, it was assumed that a clinically competent nurse could provide general health supervision, screening tests, emergency care for acutely ill and injured, health counselling, delegated medical management and referral to other health care facilities with continuity of patient care. A pilot plan was developed and money requested to demonstrate the feasibility of assigning a nurse to a "Doctorless Town" to provide primary health care services.

Included in this feasibility study which was funded from April 1, 1972 to April 30, 1973 were concomitant objectives which will at this point be viewed in the interrogative. Can this nurse providing health care services help the town to resolve its health care needs? How is the success, or unsucccess, of this program to be measured? How should the kinds of health care services needed by the residents be determined? Is one nurse able to provide them? Implicit were many other questions also, which would need to be answered as the project year began, continued and ultimately ended.

Two weeks prior to opening the clinic, leg work, telephone calls and meetings were held to establish: (1) a Medical Advisory Committee, (2) a Citizens Advisory Committee, (3) a site for the clinic facility, and (4) a meeting date to discuss health care needs with area inhabitants.

The Medical Advisory Committee was established through appointment of one physician from each clinic in the surrounding area. These doctors were responsible for approving standing medical orders and arranging for physician mentors to

*Public Health Nursing Consultant for the Minnesota State Department of Health in District 4 at Duluth, Minnesota.

This project was sponsored by the Minnesota State Department of Health. It was a component of the Northlands Regional Medical Program, Inc., supported by HEW grant #5 GO3 RM-00021. Opinions expressed represent those of the authors and do not imply official endorsement by NRMP, Inc. or the U.S. Department of Health, Education and Welfare.

provide our nurse with additional technical skills, basic understanding and recognition of the normal to distinguish from abnormal. The doctors were enthused with the concepts and readily offered their services in training. The Citizens Advisory Committee was comprised of the entire city council of Tower (five persons) and three members of the Town Board of Breitung (Soudan).

Impediments But Not Barriers

When working with multiple communities, hospitals, physicians and clinics, it is of utmost importance to remain impartial and objective. It is painful to learn this the hard way—from the viewpoint of the project as well as the individual who experiences many sleepless nights. Covert competition readily comes to the foreground in daily meaningless oversights. *All* of the persons involved in even the slightest way must be included in planning meetings or injured pride results in diminished involvement or concern or general apathy, and the project suffers.

For a full three months, project people were involved with meetings with the Citizens' Advisory Committee, physicians individually and in groups, and nurse applicants. Applications came from several states, but the majority were from Minnesota. Nursing background was varied: Masters degree nurses interested in "developing the expanding nursing role," Army corpsmen with an Associate Nurse degree, and diploma R.N.'s. All wished to become nurse practitioners in a clinic setting.

Super-Nurse and Storefront Clinic

After many interviews by the Project Director and the Citizens Advisory Committee, Mrs. Edith Trembath, R.N., a life-long Tower resident, was employed as the clinic nurse. Edith is a diploma R.N. and the mother of seven children with 14 years experience as staff second head nurse at the Virginia Municipal Hospital.

Following employment, even though still on her own time," Mrs. Trembath wished to be included in all "equipment roundups." Her suggestions were invaluable as to types of items which would be necessary or useful. The chairman of the Citizens Advisory Committee arranged for pick up of equipment and supplies, "pre-requisitioned" from scavenged items from surrounding hospitals, clinics, and the County Health Department.

The Citizens Advisory Committee made ar-

rangements for renting and redecorating a former card and gift shop for the clinic. A subcommittee of Economic Opportunity group subdivided the space and completed redecorating. The Committee and OEO group arranged for the \$75 per month rent and hired a clerk for the clinic.

For the first six weeks of her employment, Mrs. Trembath was oriented to the new position with help from physician mentors of the Medical Advisory Committee and nearby clinics. At the end of six weeks she was feeling comfortable in performing a systematic nursing assessment and complete patient history. Other acquired skills included vision and hearing screening, otoscopy, ophthalmoscopy, tonometry, airway insertion, cardiopulmonary resuscitation, auscultation, palpation and percussion. Physician mentorship sessions were continued twice weekly for several weeks after the clinic opened. Other inservice education oriented the nurse to other community resources: Family Planning, Crippled Children Services, Mental Health Center services, Genetic Counselling, etc.

The caption "Supernurse to Fill Tower-Soudan Area's Need for Medical Service" appeared in a front page newspaper article in the July 26th Duluth Tribune as a result of Edith's explanations at a St. Louis County Board of Health meeting. This epithet "Super-nurse" is one that Edith is, teasingly, not allowed to forget.

New Concept in Health Care in Minnesota

An "Open House" of the clinic facility and the independent nurse practicing as primary deliverer of health care services was attended by over 100 persons. No patients were yet being seen, but it was desired to have the people in the community visit "their" new facility and learn of the services to be offered.

Clinic hours were set at 9-12 and 1-3. From the first day 10 to 15 patients were seen daily at the clinic; home visits were made on request; and referral to the public health nursing service was made for ongoing home services and intensive counselling. Telephone communication between the clinic nurse and area physicians was constant and ongoing.

In the first six months "Super-nurse" saw 534 separate persons for a total of 1,415 visits. The majority of problems requiring attention were

blood pressure checks for patients on prescribed medication or suspected hypertension, prescribed allergy injections, eye complaints, rashes, sore throats, and prescribed immunizations. By this time the needs of the community and the expectations of the physicians were clearly evident. Both groups were obviously satisfied.

By the seventh month it was obvious that plans must be developed for continued funding after expiration of the one-year grant. Meetings with the project director, Citizens Advisory Board, business administrators of physician clinics and representatives from the Northlands Regional Medical Program were held to discuss appropriate fee schedules. A proposed expenditure budget of \$1,550 per month was developed. Several fee schedules were suggested: (1) initial visits \$7.50, including history and nursing assessment, follow up visit \$5, minimum visit \$3; (2) initial visit \$4, subsequent \$2; (3) initial \$4, subsequent \$3.

The project director felt that if the first fee schedule was adopted, Tower and Soudan payed the rent, and OEO paid the clerk, the funds would be sufficient to sustain the clinic. Plans 2 and 3 would need subsidies because of the low fees. Not wishing to "frighten away" patients, the Citizens

Advisory Committee favored low fees with financial subsidies for the remainder.

Since evaluation of resident response was needed for determining effectiveness of the project, an article was placed in the local paper soliciting comments, both pro and con, and suggestions for future fee schedules. Letters poured in for continuation of the clinic. Seventy-one individuals and six local clubs or groups responded favorably. Many indicated willingness to pay fees up to those charged by their private physicians because of convenience, mileage saved, and confidence in the competence of the nurse.

As of this writing, the City of Tower is planning to investigate legal aspects more completely but will definitely continue the clinic and have Edith as their employee. A fee system has been approved: \$3.50 per month per family, \$2 per couple over 65, and \$2 per individual office visit—*Much too low for economic stability!* The townspeople plan to seek other sources of subsidy for the balance of needed funds. They're a spunky lot who will undoubtedly find a solution to future funding, because the residents of a doctorless town have found out what in health is good for them.

LIBRARY OF THE
COLLEGE OF PHYSICIANS
OF PHILADELPHIA

This Book is due on the last date stamped below. No further preliminary notice will be sent. Requests for renewals must be made on or before the date of expiration.

DUE	DUE

A fine of twenty-five cents will be charged for each week or fraction of a week the book is retained without the Library's authorization.
